Abstract

We propose maximum likelihood (ML) and restricted maximum likelihood (REML) methods for estimating the mean and covariance parameters of multi-input multi-output (MIMO) Ricean and Rayleigh block-fading channels using measurements from multiple coherent intervals containing both amplitudes and phases of the received signal. Correlated and independent fading scenarios with structured and unstructured line-of-sight (LOS) array response models are considered. Computationally efficient ML and approximate ML (AML) estimators are proposed for unitary space-time modulation schemes and orthogonal designs in correlated fading. We also derive Cramér-Rao bounds (CRBs) for the unknown parameters, discuss initialization of the proposed algorithms, and evaluate their performance via numerical simulations under the block- and continuous-fading scenarios.

I. INTRODUCTION

Statistical modeling of multi-input multi-output (MIMO) Ricean and Rayleigh fading channels has recently attracted considerable attention, see [1]–[3] and references therein. The effects of correlated MIMO Rayleigh and Ricean fading on capacity and error-probability performance are discussed in [1]–[9]. However, it is assumed in [1]–[9] that statistical properties of the fading process are known. In [10], a method is proposed for consistent estimation of fading channel correlations in a single-input single-output frequency-selective Rayleigh fading scenario. In [11], an expectation-maximization (EM) algorithm is derived for estimating the mean and covariance parameters of a multivariate complex Ricean density from noiseless measurements and applied to polarimetric synthetic aperture radar (SAR). Most existing approaches to estimating fading-channel statistical properties do not account for noise effects and are based on signal-power measurements only, see e.g. [12], [13] and references therein. In this paper (see also [14]), we present maximum likelihood (ML) and restricted maximum likelihood (REML) methods for estimating statistical properties of MIMO Ricean and Rayleigh block-fading channels using complex noisy measurements (containing both the phases and amplitudes of the received signals) from multiple coherent intervals. Knowing these properties is beneficial for (i) performance analysis [1]–[9] and design of wireless communication systems [6], [15], [16], (ii) implementation of space-time transmit precoding schemes which utilize mean and covariance feedback (see e.g. [17] and references therein), (iii) antenna and constellation selection in spatial-multiplexing MIMO systems [18], (iv) implementation of noncoherent ML space-time receivers [5], [6], (v) mobile positioning [19], and (vi) channel
estimation and sounding\textsuperscript{1} [10], [22], [23, ch. 5.3.7]. Furthermore, the estimation methods developed herein are applicable to sensor array processing for moving arrays (which shares a similar measurement model, compare e.g. the models in [24] and Section II).

We introduce the measurement model in Section II. In Section III, expectation-conditional maximization either (ECME) algorithms\textsuperscript{2} are developed for computing the ML and REML estimates of the mean and covariance parameters of MIMO channels under correlated and independent block-fading scenarios (Sections III-A and III-B, respectively). In Section III-A.3, we derive closed-form ML and approximate ML (AML) estimators for unitary space-time modulation schemes and orthogonal designs in correlated fading. We also derive Cramér-Rao bound (CRB) expressions for the unknown parameters (Appendix E and Section III-B.1), discuss initialization of the proposed algorithms (Section III-A.1), and evaluate their performance via numerical simulations under both block- and continuous-fading scenarios (Section IV). Concluding remarks are given in Section V.

II. MEASUREMENT MODEL

We adopt a block-fading model where the fading coefficients are constant within a coherent interval, but vary randomly from one coherent interval to another. Assume that spatiotemporal measurements from $K$ coherent intervals are available. Denote by $y_k(t)$ an $n_R \times 1$ data vector received by an array of $n_R$ antennas at time $t \in \{1, 2, \ldots, N\}$ in the $k$th coherent interval, where $k \in \{1, 2, \ldots, K\}$. We consider the following measurement model:

$$
y_k(t) = H_k \phi_k(t) + e_k(t), \quad t = 1, \ldots, N, \ k = 1, \ldots, K
$$

where

- $H_k$ is the $n_R \times n_T$ channel response matrix,
- $\phi_k(t)$ is an $n_T \times 1$ vector of signals transmitted by $n_T$ transmitter antennas and received by the receiver array at time $t$, and
- $e_k(t)$ is additive white complex Gaussian noise with

$$
\mathbb{E}[e_{k_1}(t_1)e_{k_2}(t_2)^H] = \delta_{k_1,k_2}\delta_{t_1,t_2} \cdot \sigma^2 I_{n_R}.
$$

Here, $\delta_{ij}$ denotes the Kronecker delta symbol, $I_n$ the identity matrix of size $n$, and $``^H``$ the Hermitian (conjugate) transpose. We assume that the transmitted symbols are known, i.e. the coherent intervals contain

\textsuperscript{1}In particular, the channel mean and covariance parameters can be incorporated into channel estimation by utilizing the Bayesian linear-model minimum mean-square error (MMSE) estimator [20, Theorem 11.1], [21] which outperforms the classical least-squares channel estimator [10].

\textsuperscript{2}The ECME algorithms belong to the general class of EM algorithms, see [25]. The EM algorithms converge monotonically to a local or the global maximum of the likelihood function, see e.g. [25, ch. 3] and [26, ch. 12.4].
training or previously detected data. Stacking all $N$ time samples from the $k$th coherent interval into a single vector and using [27, eq. (2.11) in ch. 16], we write (2.1) as

$$y_k = Z_k h_k + e_k$$

(2.2a)

where $h_k = \text{vec} \{H_k\}$ is the $n_R n_T \times 1$ channel response vector, $y_k = [y_k(1)^T, y_k(2)^T, \ldots, y_k(N)^T]^T$ is the $n_R N \times 1$ spatiotemporal data vector, $e_k = [e_k(1)^T, e_k(2)^T, \ldots, e_k(N)^T]^T$, and

$$Z_k = \phi_k^T \otimes I_{n_R}, \quad \phi_k = [\phi_k(1) \cdots \phi_k(N)].$$

(2.2b)

Here, “$^T$” denotes a transpose, $\otimes$ the Kronecker product, and the vec operator stacks the columns of a matrix one below another into a single column vector. The $n_R N \times 1$ matrix $\Phi_k$ in (2.2b) is the signal matrix in the $k$th coherent interval; we also define the “augmented” signal matrix $Z_k$ of size $n_R N \times n_R n_T$. The “vectorized” model (2.2) is used in [5] and [6] to describe MIMO measurements from a single coherent interval.

We now decompose the channel response vector $h_k$ into a sum of the (deterministic) line-of-sight (LOS) component $h_{\text{LOS},k}$ and (random) scattering component $h_{\text{sc},k}$:

$$h_k = h_{\text{LOS},k} + h_{\text{sc},k}.$$  

(2.3)

Let us adopt the following model for the LOS component:

$$h_{\text{LOS},k} = A_{\text{LOS},k} x$$

(2.4a)

where

- $A_{\text{LOS},k}, \ k = 1, 2, \ldots, K$ are $n_R n_T \times r$ matrices and
- $x$ is an $r \times 1$ vector of unknown complex coefficients.

The model (2.4a) is fairly general and can be used to describe the LOS component when dual-polarized antenna elements are employed.

When the transmitter and receiver LOS array responses are not known and the variation of the LOS component from one coherent interval to another can be described with a simple Doppler-shift model, we select $A_{\text{LOS},k}$ as

$$A_{\text{LOS},k} = \exp(j \omega_{\text{D,LOS}} N k) \cdot I_{n_R n_T}$$

(2.4b)

where $\omega_{\text{D,LOS}}$ is the LOS Doppler shift (in radians) due to the relative movement between receiver and transmitter. We assume that $\omega_{\text{D,LOS}}$ is known, unless specified otherwise (see e.g. Figs. 4, 9, and 10 in

---

3. For the definition and properties of the Kronecker product and vec operator, see [27, ch. 16].

4. Note that $\omega_{\text{D,LOS}}$ corresponds to the continuous-time LOS Doppler shift $\Omega_{\text{D,LOS}} = \omega_{\text{D,LOS}} / \Delta t$, where $\Delta t$ is the symbol duration.
Section IV). Then, (2.4a) simplifies to $h_{\text{LOS},k} = \exp(j\omega_{\text{d,LOS}} Nk) \cdot x$, where $x$ is the $n_r n_T \times 1$ unstructured LOS array response vector; hence $r = n_r n_T$ in this case.

If the transmitter and receiver LOS array responses are known, we utilize the structured LOS array response model (see [6], [14], [28], and [29]):

$$A_{\text{LOS},k} = \exp(j\omega_{\text{d,LOS}} Nk) \cdot a_{T,\text{LOS}} \otimes a_{R,\text{LOS}}$$

(2.4c)

where $a_{T,\text{LOS}}$ and $a_{R,\text{LOS}}$ are the transmitter and receiver LOS array response vectors of dimensions $n_T \times 1$ and $n_r \times 1$, respectively. Now, (2.4a) becomes: $h_{\text{LOS},k} = a_{T,\text{LOS}} \otimes a_{R,\text{LOS}} \exp(j\omega_{\text{d,LOS}} Nk) \cdot x$, where $x = x$ is the scalar LOS complex amplitude (implying $r = 1$) and $A_{\text{LOS},k}$ is an $n_r n_T \times 1$ vector.

To describe the channel variation from one coherent interval to another, we assume that the scattering channel vectors $h_{\text{SC},k}$ are zero-mean independent, identically distributed (i.i.d.) complex Gaussian, with an $n_r n_T \times n_r n_T$ covariance matrix:

$$\Psi = \mathbb{E}[h_{\text{SC},k} h_{\text{SC},k}^H], \quad k = 1, 2, \ldots, K.$$  

(2.5)

In addition, $h_{\text{SC},k}$ and noise vectors $e_k$ are assumed to be independent, i.e. $\mathbb{E}[e_{k_1}^H h_{\text{SC},k_2}] = 0$, where $k_1, k_2 \in \{1, 2, \ldots, K\}$.

Our goal is to estimate the unknown parameters in the above model:

- the LOS coefficient vector $x$,
- spatial fading covariance matrix $\Psi$, and
- noise variance $\sigma^2$,

which are assumed to be constant over the $K$ coherent intervals. This assumption is justified by the fact that the channel mean and covariance parameters depend on large-scale variations in the scattering environment, which are typically slow (see also the discussion in e.g. [15] and [22]). Define the vector of unknown parameters:

$$\rho = [\text{Re}\{x\}^T, \text{Im}\{x\}^T, \gamma^T]^T$$

(2.6)

where

$$\gamma = [\sigma^2, \Psi^T]^T$$

(2.7)

is the vector of variance components and $\Psi$ describes a parametrization of the fading covariance matrix $\Psi$. We consider two models for $\Psi$:

(i) **unstructured (correlated fading)**

$$\Psi = [\text{Re}(\text{vech}(\Psi))^T, \text{Im}(\text{vech}(\Psi))^T]^T$$
where the correlation structure of the fading channel is completely unknown;

(ii) **diagonal (independent fading)**

\[ \Psi = \text{diag}(\psi_1, \psi_2, \ldots, \psi_{n_R n_T}) \]

and

\[ \Psi = [\psi_1, \psi_2, \ldots, \psi_{n_R n_T}]^T \]

where the fading-channel coefficients are independent with non-equal variances.

Here the vech and \( \text{vech} \) operators create a single column vector by stacking elements below the main diagonal columnwise; vech includes the main diagonal, whereas \( \text{vech} \) omits it. Note that \( \Psi \) is a valid parametrization *only if* \( \Psi \) is a positive semidefinite Hermitian matrix.

In the following, we derive ML and REML algorithms for estimating the unknown parameter vector \( \rho \) under the two fading scenarios described above. We also derive efficient algorithms for estimating \( \rho \) when \( \Phi_k \Phi_k^H \) is a constant or an identity matrix.

### III. ML and REML Estimation

We first outline the ML and REML approaches to estimating \( \rho \) and then present the proposed algorithms.

Under the measurement model in Section II, the spatiotemporal data vectors \( y_k \) are independent, complex Gaussian with means and covariances

\[
\begin{align*}
E[y_k] &= \tau_k x = Z_k A_{\text{LOS}, k} x \\
\Sigma_k(\gamma) &= \text{cov}(y_k) = E[(y_k - E[y_k])(y_k - E[y_k])^H] = Z_k \Psi Z_k^H + \sigma^2 I_{n_R N}.
\end{align*}
\]

Thus, the log-likelihood function to be maximized is the logarithm of the joint probability density function (pdf) of \( y_k, k = 1, 2, \ldots, K \):

\[ L(\rho) = -(y - \mathbf{T}x)^H \Sigma(\gamma)^{-1}(y - \mathbf{T}x) - \ln |\pi \Sigma(\gamma)| \]

(3.2)

where |·| denotes the determinant. \( y = [y_1^T, y_2^T, \ldots, y_K^T]^T \), \( \mathbf{T} = [T_1^T, T_2^T, \ldots, T_K^T]^T \) is an \( K n_R N \times r \) matrix of rank \( r \), and \( \Sigma(\gamma) \) is an \( K n_R N \times K n_R N \) block-diagonal matrix:

\[ \Sigma(\gamma) = \text{bdiag}\{\Sigma_1(\gamma), \Sigma_2(\gamma), \ldots, \Sigma_K(\gamma)\} \]

The estimate of the LOS coefficient vector \( \hat{x} \) that maximizes (3.2) for any fixed \( \gamma \) is given by

\[
\hat{x}(\gamma) = [\mathbf{T}^H \Sigma(\gamma)^{-1} \mathbf{T}]^{-1} \mathbf{T}^H \Sigma(\gamma)^{-1} y = \left[ \sum_{k=1}^K A_{\text{LOS}, k}^H W_k(\gamma) A_{\text{LOS}, k} \right]^{-1} \sum_{k=1}^K A_{\text{LOS}, k}^H W_k(\gamma) z_k
\]

(3.3)
where

\[ W_k(\gamma) = (\sigma^2 Z_k^H Z_k + Z_k^H Z_k \Psi Z_k^H Z_k)^{-1} \] (3.4a)

\[ A_{\text{LOS},k} = Z_k^H Y_k = Z_k^H Z_k A_{\text{LOS},k} \] (3.4b)

\[ z_k = Z_k^H y_k = \text{vec}(Y_k \Phi_k^H) \] (3.4c)

and

\[ Y_k = [y_k(1) \cdots y_k(N)] \]

is the spatiotemporal data matrix in the \( k \)th coherent interval. The second equalities in (3.3) and (3.4c) follow by using (A.2) in Appendix A and [27, eq. (16.2.11)], respectively. Replacing \( x \) in (3.2) with its ML estimate in (3.3) yields the concentrated log-likelihood function:

\[ L(\gamma|\hat{x}(\gamma)) = -\|y - Y \hat{x}(\gamma)\|^2 \Sigma(\gamma)^{-1} \|y - Y \hat{x}(\gamma)\| - \ln |\pi \Sigma(\gamma)| = -y^H \Pi(\gamma) y - \ln |\pi \Sigma(\gamma)| \] (3.5)

where

\[ \Pi(\gamma) = \Sigma(\gamma)^{-1} - \Sigma(\gamma)^{-1} Y [Y^H \Sigma(\gamma)^{-1} Y]^{-1} Y^H \Sigma(\gamma)^{-1}. \]

Note that (3.5) is a nonlinear function of the variance-component parameters \( \gamma \) that generally needs to be maximized using iterative algorithms. Once the ML estimate \( \hat{\gamma} \) is computed by maximizing (3.5), the ML estimate of \( x \) is obtained by substituting \( \hat{\gamma} \) into (3.3). Interestingly, closed-form solutions for the ML estimates of \( \gamma \) exist under the correlated fading scenario with constant \( \Phi_k \Phi_k^H \), see Section III-A.3.

We now introduce the REML method for estimating the unknown variance components. The REML estimate of \( \gamma \) is obtained by filtering out the deterministic Ricean component from the received data, and applying ML estimation to the error contrasts (i.e. filtered data), which corresponds to maximizing the REML log-likelihood function (see Appendix B)

\[ L_{\text{REML}}(\gamma) = L(\gamma|\hat{x}(\gamma)) - \ln |Y^H \Sigma(\gamma)^{-1} Y| = L(\gamma|\hat{x}(\gamma)) - \ln \left| \sum_{k=1}^{K} Y_k^H \Sigma_k(\gamma)^{-1} Y_k \right| \] (3.6)

with respect to \( \gamma \), where \( L(\gamma|\hat{x}(\gamma)) \) is the concentrated log-likelihood in (3.5). We can also derive (3.6) by using an integrated-likelihood approach for eliminating nuisance parameters [30]; here we treat \( x \) as a nuisance parameter vector and integrate it out using a noninformative prior\(^5\), see [31, ch. 3.3.3]. The REML method provides only estimates of the variance components \( \gamma \); however, a good estimate of \( x \) is obtained by substituting the REML estimate of \( \gamma \) into (3.3), which we call the “REML” estimate of \( x \) (with a slight abuse

\(^5\)Choices of a noninformative prior pdf for \( x \) could be a complex Gaussian with an arbitrary mean and a covariance matrix whose inverse is a zero matrix, or \( \text{Re}\{x\}, \text{Im}\{x\} \in \text{uniform}(-\infty, \infty) \), see [31, p. 84].
of terminology). Since the Ricean component has been filtered out, the REML estimate of $\gamma$ is invariant to the value of $x$, i.e. changing $x$ does not alter the REML estimate of $\gamma$. Finally, the REML estimates of the variance components have smaller bias than the corresponding ML estimates, see [31] and [32].

In Appendix E, we compute general CRB expressions for the unknown parameters $\rho$ assuming an arbitrary parametrization $\psi = \psi(\psi)$ of the fading covariance matrix. We then specialize these general results to the independent and correlated fading scenarios with constant $\Phi_k \Phi_k^H$ (e.g. equal to the identity matrix), see (3.23) in Section III-B.1 and Appendices E-B and E-A.

A. Correlated Fading
We compute the ML and REML estimates of the unknown parameters under the correlated fading scenario. ECME algorithms for arbitrary $\Phi_k \Phi_k^H$ are presented in Sections III-A.1 and III-A.2. In Section III-A.3, we derive an alternating-projection ML algorithm for the case where $\Phi_k \Phi_k^H$ are independent of $k$.

1) ECME Algorithm for ML Estimation: In Appendix C-A, we derive an ML ECME algorithm for estimating $\rho$ under the correlated fading scenario. An ECME algorithm maximizes either the expected complete-data log-likelihood function (where the expectation is computed with respect to the conditional distribution of the unobserved data given the observed measurements) or the actual observed-data log-likelihood, see [25, ch. 5.7], [33], and [34]. Here, we treat the scattering channel vectors $h_{sc,k}$, $k = 1, 2, \ldots, K$ as the unobserved (or missing) data and derive the following ECME algorithm: iterate between

$$W_k^{(i)} = \left[(\sigma^2)^{(i)} Z_k^H Z_k + Z_k^H Z_k \psi^{(i)} Z_k^H Z_k\right]^{-1}$$

$$x^{(i)} = \left(\sum_{k=1}^{K} A_{LOS,k}^H W_k^{(i)} A_{LOS,k}\right)^{-1} \sum_{k=1}^{K} A_{LOS,k}^H W_k^{(i)} z_k$$

$$h_{sc,k}^{(i)} = \psi^{(i)} Z_k^H Z_k W_k^{(i)} (z_k - A_{LOS,k} x^{(i)})$$

for $k = 1, 2, \ldots, K$, and

$$(\sigma^2)^{(i+1)} = \tilde{\sigma}^2 + \frac{\sigma^2}{K \eta_0 N} \sum_{k=1}^{K} (z_k - A_{LOS,k} x^{(i)})^H W_k^{(i)} (z_k - A_{LOS,k} x^{(i)})$$

$$\psi^{(i+1)} = \psi^{(i)} + \frac{1}{K} \sum_{k=1}^{K} \left\{ h_{sc,k}^{(i)} (h_{sc,k}^{(i)})^H - \psi^{(i)} Z_k^H Z_k W_k^{(i)} Z_k^H Z_k \psi^{(i)} \right\}$$

where

$$\tilde{\sigma}^2 = \frac{1}{K \eta_0 N} \sum_{k=1}^{K} [y_k^H y_k - z_k^H (Z_k^H Z_k)^{-1} z_k] = \frac{1}{K \eta_0 N} \sum_{k=1}^{K} \text{tr} \left\{ Y_k \left[I_N - \Phi_k^H (\Phi_k \Phi_k^H)^{-1} \Phi_k\right] Y_k^H \right\}.$$
(estimated) Bayesian linear-model MMSE estimators of the scattering channel vectors $h_{sc,k}$, with $x$, $\Psi$, and $\sigma^2$ replaced by their $i$th-iteration estimates (see also footnote 1). To derive the second equality in (3.8c), we have used the property of the $\text{vec}$ operator in [27, Theorem 16.2.2].

**Initialization:** The above iteration can be initialized with $\Psi^{(-1)} = 0$, implying that the initial estimate $x^{(-1)}$ of the LOS coefficient vector is simply its linear least-squares (LS) estimate [see also (3.3)]:

$$x^{(-1)} = \left( \sum_{k=1}^{K} T_k^H T_k \right)^{-1} \sum_{k=1}^{K} T_k^H y_k = \left( \sum_{k=1}^{K} A_{los,k}^H Z_k^H Z_k A_{los,k} \right)^{-1} \sum_{k=1}^{K} A_{los,k}^H z_k. \quad (3.9)$$

After computing $x^{(-1)}$, a good initial estimate of $\Psi$ is its modified method-of-moments estimate (similar to [35, p. 244]):

$$\Psi^{(0)} = \frac{1}{K} \sum_{k=1}^{K} (Z_k^H Z_k)^{-1} \left( z_k - A_{los,k} x^{(-1)} \right) \left( z_k - A_{los,k} x^{(-1)} \right)^H (Z_k^H Z_k)^{-1} - \min\{ (\sigma^2)^{(0)}, \hat{\lambda} \} \cdot \frac{1}{K} \sum_{k=1}^{K} (Z_k^H Z_k)^{-1} \quad (3.10a)$$

where $(\sigma^2)^{(0)}$ is a method-of-moments estimate of $\sigma^2$:

$$\left( \sigma^2 \right)^{(0)} = \frac{1}{K n_r (N - n_r)} \sum_{k=1}^{K} \left[ y_k^H y_k - z_k^H (Z_k^H Z_k)^{-1} z_k \right] = \frac{K n_r N}{K n_r (N - n_r)} \cdot \bar{\sigma}^2 \quad (3.10b)$$

which is a good initial estimate of $\sigma^2$, and $\hat{\lambda}$ is the smallest generalized eigenvalue of the matrices $(1/K) \cdot \sum_{k=1}^{K} (Z_k^H Z_k)^{-1} (z_k - A_{los,k} x^{(-1)}) (z_k - A_{los,k} x^{(-1)})^H (Z_k^H Z_k)^{-1}$ and $(1/K) \cdot \sum_{k=1}^{K} (Z_k^H Z_k)^{-1}$. Note that $(Z_k^H Z_k)^{-1}$ can be efficiently computed as

$$(Z_k^H Z_k)^{-1} = (\Phi_k^* \Phi_k^T)^{-1} \otimes I_{n_r}.$$
2) ECME Algorithm for REML Estimation: In Appendix C-B, we derive an ECME algorithm for REML estimation of $\rho$, which follows by replacing (3.8a) and (3.8b) with

\[
(\sigma^2)^{(i+1)} = \frac{Kn_r N}{Kn_r N - r} \sigma^2 + \frac{(\sigma^2)^{(i)}}{Kn_r N - r} \sum_{k=1}^{K} (z_k - A_{\text{LOS,k}} x^{(i)})^H W_k^{(i)} (z_k - A_{\text{LOS,k}} x^{(i)})
\]

(3.11a)

\[
\psi^{(i+1)} = \psi^{(i)} + \frac{1}{K} \sum_{k=1}^{K} \left\{ h_{sc,k}^H (h_{sc,k})^H - \psi^{(i)} z_k^H z_k \left[ W_k^{(i)} - W_k^{(i)} A_{\text{LOS,k}} \left( \sum_{l=1}^{K} A_{\text{LOS,l}}^H W_l^{(i)} A_{\text{LOS,l}} \right)^{-1} A_{\text{LOS,k}}^H W_k^{(i)} \right] Z_k^H Z_k \psi^{(i)} \right\}
\]

(3.11b)

in the iteration (3.7)–(3.8) and keeping the other steps intact.

The above ML and REML ECME algorithms always converge to estimates that are in the parameter space: $(\sigma^2)^{(i)} \geq 0$ and $\psi^{(i)} \geq 0$ (i.e. $\psi^{(i)}$ is positive semidefinite) at each iteration step $i$, provided that the initial values are in the parameter space. This is an important general property of the EM and related algorithms (such as ECME), see [26, ch. 12.4]. The fact that $\psi^{(i+1)} \geq 0$ in (3.8b) follows from the derivation in Appendix C, see equations (C.4) and (C.7) and observe that a sample covariance matrix is always positive semidefinite. Similar argument applies to the REML case since the ECME REML algorithm is simply the ECME ML algorithm applied to the error contrasts. Rayleigh-fading versions of the above algorithms are obtained by removing the step (3.7b) and setting $A_{\text{LOS,k}} = 0$ in (3.7c) and (3.8a) or (3.11a).

3) ML Estimation for Constant $\phi_k \phi_k^H$: We now present computationally efficient estimators for the scenario where

\[
\phi_k \phi_k^H = \Gamma_\phi = \text{constant}
\]

(3.12a)

(independent of $k \in \{1, 2, \ldots, K\}$), which holds for many practically important signaling schemes, e.g. unitary space-time codes [36] and space-time block codes based on orthogonal designs [37], [38]. The above condition implies that $Z_k^H Z_k$ also does not depend on $k$; hence, we define

\[
C = Z_k^H Z_k = \Gamma_\phi^T \otimes I_{n_r}
\]

(3.12b)

In this case, there exists a closed-form expression for the ML estimate of $\sigma^2$ (see Appendix D):

\[
\sigma_{\text{ML}}^2 = \frac{1}{Kn_r (N - n_T)} \sum_{k=1}^{K} (y_k^H y_k - z_k^H C^{-1} z_k) = \frac{1}{Kn_r (N - n_T)} \sum_{k=1}^{K} \text{tr} \left[ Y_k (I_N - \phi_k^H \Gamma_\phi^{-1} \phi_k) Y_k^H \right]
\]

(3.13)
which coincides with the moment estimator in (3.10b). The exact ML estimates of $x$ and $\Psi$ can be computed by iterating between the following two steps (see Appendix D):

$$W^{(i)} = (\hat{\sigma}_{ml}^2 C + C \Psi^{(i)} C)^{-1}$$  \hspace{1cm} (3.14a)

$$x^{(i)} = \left[ \sum_{k=1}^{K} A_{LOS,k}^H W^{(i)} A_{LOS,k} \right]^{-1} \sum_{k=1}^{K} A_{LOS,k}^H W^{(i)} z_k$$  \hspace{1cm} (3.14b)

$$\xi_k^{(i)} = C^{-1} (z_k - A_{LOS,k} x^{(i)}) = \text{vec} \left( Y_k \Phi_k^H \Gamma_{\Phi}^{-1} \right) - A_{LOS,k} x^{(i)}$$  \hspace{1cm} (3.14c)

for $k = 1, 2, \ldots, K$, and

$$\Psi^{(i+1)} = \left[ \frac{1}{K} \sum_{k=1}^{K} \xi_k^{(i)} \left( \xi_k^{(i)} \right)^H \right] - \hat{\sigma}_{ml}^2 \cdot (\Gamma_{\Phi})^{-1} \otimes I_{NR}.$$  \hspace{1cm} (3.15)

The above iteration increases the log-likelihood function (3.2) at each cycle but may converge to solutions that are not in the parameter space, see also the discussion below. It can be shown that, if (3.12) holds, the estimators (3.13) and (3.15) are fixed points of the ECME iterations (3.8a) and (3.8b).

In Appendix E-A, we derive the CRB expressions for this scenario.

**ML Estimation for Unstructured LOS Array Response Model:** Under the unstructured LOS array response model,

$$\hat{x}_{UML} = C^{-1} \cdot \frac{1}{K} \sum_{k=1}^{K} \exp(-j\omega_{D,LOS}Nk) z_k = \frac{1}{K} \sum_{k=1}^{K} \text{vec} \left( Y_k \Phi_k^H \Gamma_{\Phi}^{-1} \right) \exp(-j\omega_{D,LOS}Nk)$$  \hspace{1cm} (3.16a)

$$\hat{\Psi}_{UML} = \left[ \frac{1}{K} \sum_{k=1}^{K} \tilde{\xi}_k \tilde{\xi}_k^H \right] - \hat{\sigma}_{ml}^2 \cdot (\Gamma_{\Phi})^{-1} \otimes I_{NR}$$  \hspace{1cm} (3.16b)

are the closed-form expressions for the ML estimates of $x$ and $\Psi$, where $\hat{\sigma}_{ml}^2$ is the ML estimate of $\sigma^2$ in (3.13) and

$$\tilde{\xi}_k = \text{vec} \left( Y_k \Phi_k^H \Gamma_{\Phi}^{-1} \right) - \exp(j\omega_{D,LOS}Nk) \cdot \hat{x}_{UML}$$  \hspace{1cm} (3.16c)

for $k = 1, 2, \ldots, K$. Here, (3.16a) follows by substituting (2.4b) into (3.3) [see also (3.4b) and (3.12b)] and (3.16b) is obtained by substituting $\hat{x}_{UML}$ into (D.2c), see Appendix D.

If the LOS Doppler shift $\omega_{D,LOS}$ is unknown, its ML estimate can be computed by maximizing the following concentrated log-likelihood function:

$$\hat{\omega}_{D,LOS} = \arg \max_{\omega_{D,LOS}} z_{\text{DTFT}}(\omega_{D,LOS}N)^H \left( \sum_{k=1}^{K} z_k z_k^H \right)^{-1} z_{\text{DTFT}}(\omega_{D,LOS}N)$$  \hspace{1cm} (3.17)

where

$$z_{\text{DTFT}}(\omega) = \frac{1}{K} \cdot \sum_{k=1}^{K} \exp(-j\omega k) z_k = \frac{1}{K} \cdot \sum_{k=1}^{K} \exp(-j\omega k) \text{vec} \left( Y_k \Phi_k^H \right)$$  \hspace{1cm} (3.18)
is proportional to the discrete-time Fourier transform (DTFT) of \( z_k, k = 1, 2, \ldots, K \). The above concentrated log-likelihood is obtained by replacing \( \mathbf{x}, \Psi, \sigma^2 \) and \( Z_k^H Z_k \) in (A.3) (see Appendix A) with \( \hat{\mathbf{x}}_{\text{UML}}, \hat{\Psi}_{\text{UML}}, \hat{\sigma}^2_{\text{ML}} \) and \( C \) (respectively), neglecting constant terms, using [27, Theorem 18.1.1 at p. 416]), and applying a monotonic transformation. The classical algorithm for DTFT-based frequency estimation in [39, ch. 6.4.4] can be easily extended and applied to maximizing (3.17).

**AML Estimation for Structured LOS Array Response Model:** Due to the CRB decoupling between the mean and variance-component parameters [see (E.1a) in Appendix E], the ML estimate of \( \Psi \) for the unstructured LOS array response model in (3.16b) is asymptotically efficient under the structured LOS array response model. Hence, \( \hat{\Psi}_{\text{UML}} \) is an AML estimate of \( \Psi \), provided that it is positive semidefinite. Now, we obtain a closed-form AML estimate of the structured-array complex LOS amplitude by substituting (2.4c) and \( \hat{\sigma}^2_{\text{ML}} \) and \( \hat{\Psi}_{\text{UML}} \) into (3.3):

\[
\hat{\mathbf{x}}_{\text{AML}} = \left( \frac{a_{T,\text{LOS}}^H \otimes a_{R,\text{LOS}}^H}{a_{T,\text{LOS}}^H \otimes a_{R,\text{LOS}}^H} C^{-1} \right) \mathbf{z}_{\text{DTFT}} - \mathbf{z}_{\text{DTFT}} \mathbf{z}_{\text{DTFT}}^H (3.19a)
\]

where

\[
\Xi = \left[ \frac{1}{K} \sum_{k=1}^{K} z_k z_k^H \right] - \mathbf{z}_{\text{DTFT}} \mathbf{z}_{\text{DTFT}}^H (3.19b)
\]

To simplify the notation, we have omitted the dependence of \( \mathbf{z}_{\text{DTFT}}(\omega_{d,\text{LOS}} N) \) on \( \omega_{d,\text{LOS}} N \) in (3.19). The above estimator is asymptotically efficient. However, it is based on the assumption that \( \hat{\Psi}_{\text{UML}} \geq 0 \) and performs poorly when this assumption does not hold (e.g. when \( K \) is small, see Figs. 2, 6, and 8 in Section IV).

**ML Estimation for Rayleigh Fading:** Under the Rayleigh-fading scenario, the closed-form expressions for the ML estimates of \( \sigma^2 \) and \( \Psi \) are given by (3.13) and

\[
\hat{\Psi}_{\text{ML}} = \left[ \frac{1}{K} \sum_{k=1}^{K} \text{vec} (Y_k \Phi_k^H \Gamma_{\Phi}^{-1}) \cdot \text{vec} (Y_k \Phi_k^H \Gamma_{\Phi}^{-1})^H \right] - \hat{\sigma}^2_{\text{ML}} \cdot (\Gamma_{\Phi}^T)^{-1} \otimes I_{\eta R}. (3.20)
\]

The closed-form ML estimates in (3.13), (3.16), and (3.20) can be used to implement noncoherent ML space-time receivers, which require fast estimation of the fading parameters.

The estimates of \( \Psi \) obtained using (3.14)–(3.15) and closed-form expressions (3.16b) and (3.20) are maximum likelihood only if they are positive semidefinite; otherwise, we can apply the ECME algorithm in Section III-A.1 which always converges to solutions within the parameter space. Clearly, a necessary condition for (3.15), (3.16b), and (3.20) to be positive semidefinite is: \( K \geq n_R n_T \). The probability that (3.14)–(3.15), (3.16b), and (3.20) yield non-positive semidefinite estimates of \( \Psi \) is asymptotically zero as either \( K \to \infty \) or \( N n_R \to \infty \). For the unstructured LOS array response model, we can remove (3.7b) from the ML and REML ECME iterations and use the closed-form expression for the ML estimate of \( \mathbf{x} \) in (3.16a).
\textbf{B. Independent Fading}

We develop ECME ML and REML algorithms for estimating $\rho$ under the independent fading scenario and simplify them in the case where $\Phi_k \Phi_k^H$ is an identity matrix. Approximately independent fading occurs, for example, in virtual channel representations, see [22] and references therein. (In [14], we derived Henderson’s methods [40] for this scenario which performed similarly to the algorithms proposed here.)

1) \textit{ECME Algorithm for ML Estimation:} The ECME ML algorithm for independent fading follows using arguments similar to those in Appendix C-A (where ECME algorithms were derived for the correlated fading scenario): iterate between (3.7a)--(3.7c) for $k = 1, 2, \ldots, K$ and

\begin{align}
\left(\sigma^2\right)^{(i+1)} &= \bar{\sigma}^2 + \frac{\left(\sigma^2\right)^{(i)}}{K n_R N} \sum_{k=1}^{K} (z_k - A_{LOS,k} x^{(i)})(z_k - A_{LOS,k} x^{(i)})^H \tag{3.21a}
\end{align}

\begin{align}
\left(\psi_n\right)^{(i+1)} &= \left(\psi_n\right)^{(i)} + \frac{1}{K} \sum_{k=1}^{K} \left( \frac{\left|\left|h_{k,c,k}\right| \right|}{n} - \frac{\left|\left(\psi_n\right)^{(i)}\right|}{n} \cdot \left|Z_k^H Z_k W^{(i)}_k Z_k^H Z_k \right|_{n,n} \right) \tag{3.21b}
\end{align}

for $n = 1, 2, \ldots, n_R n_T$, where $\bar{\sigma}^2$ has been defined in (3.8c) and

\[ \psi^{(i)} = \text{diag}\{\left(\psi_1\right)^{(i)}, \left(\psi_2\right)^{(i)}, \ldots, \left(\psi_{n_R n_T}\right)^{(i)}\}. \]

Here $| \cdot |$ denotes absolute value, $[Z_k^H Z_k W^{(i)}_k Z_k^H Z_k]_{n,n}$ the $(n,n)$ element of $Z_k^H Z_k W^{(i)}_k Z_k^H Z_k$, and $[h_{k,c,k}]_n$ the $n$th element of $h_{k,c,k}$.

$\Phi_k \Phi_k^H = I_{n_T}$: When $\Phi_k \Phi_k^H = I_{n_T}$, (3.7a) and (3.7c) simplify to

\begin{align}
W^{(i)} &= W^{(i)}_k = \text{diag}\left\{ \left(\sigma^2\right)^{(i)} + \left(\psi_n\right)^{(i)-1}, \ldots, \left(\sigma^2\right)^{(i)} + \left(\psi_{n_R n_T}\right)^{(i)-1} \right\} \tag{3.22a}
\end{align}

\begin{align}
[h_{k,c,k}]_n &= \frac{\left(\psi_n\right)^{(i)}}{\left(\sigma^2\right)^{(i)} + \left(\psi_n\right)^{(i)}} \cdot (z_k - A_{LOS,k} x^{(i)})_n \tag{3.22b}
\end{align}

for $n = 1, 2, \ldots, n_R n_T$, and the conditional maximization (CM) steps in (3.21a) and (3.21b) simplify accordingly. In this case, the CRB expressions also simplify (see Appendix E-B):

\begin{align}
[\text{CRB}_{\sigma^2, \sigma^2} = & \frac{\sigma^4}{n_R (N - n_T) K} \tag{3.23a} \\
[\text{CRB}_{\psi, \psi} = & \frac{(\sigma^2 + \psi_n)^2}{K} + \frac{\sigma^4}{n_R (N - n_T) K} \tag{3.23b}
\end{align}

for $n = 1, 2, \ldots, n_R n_T$. Here, $\text{CRB}_{\psi, \psi}$ is an increasing function of both $\sigma^2$ and $\psi_n$. As expected, both $\text{CRB}_{\sigma^2, \sigma^2}$ and $\text{CRB}_{\psi, \psi}$ decrease proportionally to $1/K$ as the number of coherent intervals $K$ grows.
2) **ECME Algorithm for REML Estimation:** The ECME REML algorithm for independent fading follows using arguments similar to those in Appendix C-B: iterate between (3.7a)–(3.7c) for \(k = 1, 2, \ldots, K\) and
\[
(\sigma^2)^{(i+1)} = \frac{K n_r N}{K n_r N - r} \cdot \sigma^2 + \frac{(\sigma^2)^{(i)}}{K n_r N - r} \cdot \sum_{k=1}^{K} (z_k - A_{\text{LOS},k} x^{(i)} W_k^H (z_k - A_{\text{LOS},k} x^{(i)})) \tag{3.24a}
\]
\[
(\psi)^{(i+1)} = (\psi)^{(i)} + \frac{1}{K} \cdot \sum_{k=1}^{K} \left\{ \left( [h_{\text{sc},k}]_n \right)^2 - [([\psi])^{(i)}]_n \right\} \cdot Z_k^H Z_k \left( W_k^H - W_k^H A_{\text{LOS},k} \right) \cdot \left( \sum_{l=1}^{K} A_{\text{LOS},l}^H W_l^H A_{\text{LOS},l}^{-1} A_{\text{LOS},l}^H W_l^H Z_k^H Z_k \right)_{n,n} , \quad n = 1, 2, \ldots, n_r n_t. \tag{3.24b}
\]
For \(\Phi_k \Phi_k^H = I_{n_t}\), we can use (3.22) to simplify (3.24a) and (3.24b).

As in the correlated fading case, the above ECME algorithms converge to variance estimates that are always in the parameter space (i.e. non-negative). They can be initialized using the moment estimators in (3.10b) and diagonal elements of (3.10a). For the unstructured LOS array response model, we can remove (3.7b) from the ML and REML ECME iterations and use the closed-form expression for the ML estimate of \(x\) in (3.16a). Rayleigh-fading versions of these algorithms follow by removing (3.7b) and setting \(A_{\text{LOS},k} = 0\) in (3.7c) and (3.21a) or (3.24a).

**IV. Numerical Examples**

We evaluate the estimation accuracy and computational efficiency of the ML and REML methods in Section III. Our performance metric is the mean-square error (MSE) of an estimator, calculated using 5000 independent trials. Numerical simulations were performed using both block- and continuous-fading scenarios. Throughout this section, we employed the Alamouti transmission scheme for a \(n_r \times n_t = 2 \times 2\) MIMO system with \(N = 30\) quadrature phase-shift keying (QPSK) symbols per coherent interval (normalized so that \(\Phi_k \Phi_k^H = I_2\)) and generated additive white complex Gaussian noise \(e_k(t)\) with variance \(\sigma^2 = 0.01\).

**A. Block-Fading Scenario**

In the block-fading case, we generated the simulated data using the measurement model in Section II. The LOS component was generated using (2.4c) with \(x = 1\), \(a_r,LOS = [1, \exp(-j\pi/6)]^T\), \(a_h,LOS = [1, \exp(-j\pi/3)]^T\), and \(\omega_{d,LOS} = \pi/2 \cdot 10^{-2}\).

1) **Correlated Fading:** In the first set of simulations, we consider the correlated block-fading scenario and apply the ML and REML algorithms in Section III-A using the unstructured and structured LOS array response models in (2.4b) and (2.4c). The spatial fading covariance matrix was:
\[
\Psi = \sigma^2 \begin{bmatrix}
1 & 0.2 + 0.1 j & 0.4 - 0.5 j & 0 \\
0.2 - 0.1 j & 2 & 0 & 0.1 + 0.1 j \\
0.4 + 0.5 j & 0 & 4 & 0.3 - 0.3 j \\
0 & 0.1 - 0.1 j & 0.3 + 0.3 j & 8
\end{bmatrix}. \tag{4.1}
\]
Fig. 1. Mean-square errors and Cramér-Rao bounds for the ML and REML estimates of \(\text{Re}\{\Psi_{3,2}\}, \Psi_{3,3}, \Psi_{4,4}\), and sum of all elements of \(\psi\) under the correlated block-fading scenario and unstructured (left) and structured (right) LOS array response models, as functions of \(K\).

In Figs. 1 and 2, we present the MSEs (and corresponding CRBs) for the ML and REML estimates of selected parameters as functions of the number of coherent intervals \(K\). The ML estimates of \(\rho\) were computed using the closed-form expressions in (3.13) and (3.16) for the unstructured LOS model and the alternating-projection ML algorithm (3.14)–(3.15) for the structured LOS model. For \(K \geq 10\), the alternating-projection algorithm converged in less than five iterations. In the cases where (3.16b) and (3.15) were not positive semidefinite, we ran the ECME ML algorithm described in Section III-A.1. In terms of CPU time, the alternating-projection ML algorithm was five to seven times faster than the ECME ML algorithm. The REML estimation was performed using the ECME algorithm in Section III-A.2 which converged in less than seven iterations.

In Table I, we show the percentages of trials in which the estimates of \(\Psi\) in (3.15) and (3.16b) were not positive semidefinite, as functions of \(K\). These percentages decay rapidly with \(K\); however, they are high for small \(K\), underlining the importance of the ECME approach which handles parameter constraints automatically.

In Fig. 1, the MSEs and CRBs for the ML and REML estimates of \(\text{Re}\{\Psi_{3,2}\}, \Psi_{3,3}, \Psi_{4,4}\), and sum of all elements of \(\psi\) are shown as functions of \(K\) for the unstructured (left) and structured (right) LOS array.

Fig. 2. MSEs and CRBs for the ML and REML estimates of the LOS coefficients under the correlated block-fading scenario and unstructured (left) and structured (right) LOS array response models, as functions of $K$.

response models. Due to the CRB decoupling between the mean and variance-component parameters [see (E.1a) in Appendix E], the CRBs for the variance components are the same regardless of the LOS array response parametrization; the corresponding MSEs are also approximately equal.

In Fig. 2, we present the MSEs and CRBs for the ML and REML estimates of the unstructured LOS array response vector (left) and ML, REML, AML, and LS estimates of the structured-array LOS complex amplitude $x$ (right), as functions of $K$. Here, the linear LS estimate of $x$ is computed by substituting (2.4c) into (3.9). As expected, the MSEs and CRBs are smaller for the structured LOS model. For larger $K$, the (closed-form) AML and (iterative) ML and REML estimates of $x$ achieve similar MSE performances. However, the AML estimator performs poorly when $K$ is small, see also the discussion in Section III-A.3.
An analytical expression for the MSE of the linear LS estimate of $x$ is given below (for the special case of $\Phi_k \phi_k^H = I_n$ and assuming the block-fading scenario):

$$
\text{MSE}_x = \text{MSE}_{\text{Re}(x)} + \text{MSE}_{\text{Im}(x)} = \frac{\sigma^2}{K \cdot a_r^H a_r} + \frac{(a^H_{\text{T,LOS}} \otimes a^H_{\text{T,LOS}}) \psi (a_{\text{T,LOS}} \otimes a_{\text{T,LOS}})}{K \cdot (a^H_{\text{T,LOS}})^2 \cdot (a^H_{\text{T,LOS}})^2}.
$$

The CRBs were computed using the results in Appendix E-A.

Since the MSE performances of the ML and REML estimators are similar, it is of interest to compare their biases as well. Figure 3 compares the absolute biases for the ML and REML estimates of the variance components $\psi$ (computed using 5000 independent trials) under the unstructured (left) and structured (right) LOS array response models; the biases are shown as functions of $K$. The obtained results confirm the bias-correction property of REML variance-component estimation, see also the discussion in Section III. Compared with ML, the REML approach yields significant bias improvements when the rank $r$ of the deterministic component is large (e.g. unstructured LOS array model) and for small sample sizes $K$.

Unknown $\omega_{\text{D,LOS}}$: If the LOS Doppler shift $\omega_{\text{D,LOS}}$ is unknown, we estimate it using the ML estimator in (3.17) for the unstructured LOS model. Figure 4 shows the MSE performance of this estimator as a function of $K$. 

---

Fig. 3. Absolute biases for the ML and REML estimates of the sum of all elements of $\psi$ under the correlated block-fading scenario and unstructured (left) and structured (right) LOS array response models, as functions of $K$. 

---
2) Independent Fading: Consider the independent block-fading scenario with the following fading covariance matrix:

\[ \Psi = \text{diag}\{\psi_1, \psi_2, \psi_3, \psi_4\} = \sigma^2 \cdot \text{diag}\{1, 2, 4, 8\}. \]  

\( (4.3) \)

We have applied the ECME ML and REML algorithms in Section III-B; their MSE performances are shown in Figs. 5 and 6. For \( K \geq 20 \), the ECME algorithms converged in less than ten iterations. Figure 5 shows the MSEs and CRBs for the ML and REML estimates of the fading variances \( \psi_1, \psi_2, \psi_3, \) and \( \psi_4 \) as functions of \( K \) for the unstructured (left) and structured (right) LOS array response models. As expected, the CRBs for these variances are the same regardless of the LOS array response parametrization and the corresponding MSEs are approximately equal as well. In Fig. 6, we compare the MSEs and CRBs for the ML and REML estimates of the unstructured LOS array response vector (left) and ML, REML, AML, and LS estimates of the structured-array LOS complex amplitude \( x \) (right). To compute the CRBs, we used (3.23) and the results in Appendix E-B.

B. Continuous-Fading Scenario

We now study the performance of the proposed methods in continuous fading where the scattering channel coefficients are temporally correlated according to the Jakes’ model, see e.g. [12], [41] and references therein. First, denote by \( h_{sc,k}(t) \) the scattering channel vector at time \( t \) in the \( k \)th coherent interval. Assuming adjacent coherent intervals, we model the \( K n_r n_t N \times 1 \) vector of all scattering coefficients: \( h_{sc} = [h_{sc,1}(1)^T \cdots h_{sc,1}(N)^T, h_{sc,2}(1)^T \cdots h_{sc,2}(N)^T \cdots h_{sc,K}(1)^T, \cdots h_{sc,K}(N)^T]^T \) as a zero-mean complex Gaussian vector with covariance matrix (see [41]):

\[ \mathbb{E} [h_{sc} h_{sc}^H] = J(\omega_0) \otimes \Psi \]  

\( (4.4a) \)
where $\omega_d \in (0, \pi)$ is the maximum angular Doppler frequency (corresponding to the Doppler spread of $2\omega_d$), the $(p, q)$ element of the $KN \times KN$ matrix $J(\omega_d)$ is

$$[J(\omega_d)]_{p,q} = J_0(\omega_d(p - q))$$

(4.4b)

and $J_0(\cdot)$ denotes the zeroth-order Bessel function of the first kind [12], [41]. We further assume that the LOS component of the channel response matrix changes with $t$ according to the following model:

$$H_{\text{LOS},k}(t) = a_{R,\text{LOS}} a_{T,\text{LOS}}^T \exp\{j \omega_{\text{D,LOS}} \cdot [(k - 0.5) N + t]\} \cdot x$$

(4.4b)

where the LOS angular Doppler shift $\omega_{\text{D,LOS}}$ should be bounded by the maximum Doppler frequency, i.e. $|\omega_{\text{D,LOS}}| \leq \omega_d$. Combining the scattering and LOS channel components, we obtain the following *continuous-fading measurement model*:

$$y_k(t) = [H_{\text{SC},k}(t) + H_{\text{LOS},k}(t)] \phi_k(t) + e_k(t)$$

(4.4c)

for $t = 1, \ldots, N$, $k = 1, \ldots, K$, where $\phi_k(t)$ and $e_k(t)$ have been defined in Section II and $h_{\text{SC},k}(t) = \text{vec} \{H_{\text{SC},k}(t)\}$. The above model accounts for correlations among the coherent intervals and time variations of the scattering and LOS channel coefficients within a coherent interval.
Fig. 6. MSEs and CRBs for the ML, REML, AML, and LS estimates of the LOS coefficients under the independent block-fading scenario and unstructured (left) and structured (right) LOS array response models, as functions of $K$.

In the following examples, we consider the correlated fading scenario with $\Psi$ given in (4.1), maximum Doppler frequency $\omega_D = 2\pi \cdot 10^{-2}$ (consistent with the mobile speed of 100 mi/h for the carrier frequency 1.9 GHz and a symbol rate of 30 kHz, see also [36]), and the LOS parameters $x = 1$, $a_{T,LOS} = [1, \exp(-j\pi/6)]^T$, $a_{R,LOS} = [1, \exp(-j\pi/3)]^T$, and $\omega_{D,LOS} = \pi/2 \cdot 10^{-2}$. We first assume that the LOS Doppler shift $\omega_{D,LOS}$ is known, and then consider the case where $\omega_{D,LOS}$ is unknown.

**Known $\omega_{D,LOS}$:** We computed the ML and REML estimates of $\rho$ using the methods in Section III-A where the coherent-interval length was chosen as $N = 30$. Figures 7 and 8 show the MSEs for the ML and REML estimates of $\text{Re}\{\psi_{3,2}\}$, $\psi_{3,3}$, $\psi_{4,4}$, sum of all elements of $\psi$, and the LOS coefficients, as functions of $K$; Figure 8 (right) shows the MSEs for the AML and LS estimates of the structured-array LOS complex amplitude $x$. We also compare these MSEs with the corresponding block-fading CRBs, thus quantifying the performance loss that each method incurs due to continuous fading. Interestingly, for small $K$ the MSEs of the ML and REML estimates are close to the block-fading CRBs. Under the continuous-fading scenario, the proposed variance-component estimates are mostly affected by correlations among the coherent intervals and time variations of the scattering component within a coherent interval, whereas the LOS-coefficient estimates...
are mostly affected by time variations of the LOS component.

Unknown \( \omega_{\text{D,LOS}} \): We now consider the scenario where the LOS Doppler shift \( \omega_{\text{D,LOS}} \) is unknown and estimated by maximizing (3.17). Here, we selected the coherent interval length \( N = 30 \) as in the previous example. Following the estimated likelihood approach in e.g. [26, ch. 10.7], we treat the obtained estimate of \( \omega_{\text{D,LOS}} \) as a known constant and apply the ML and REML methods in Section III-A. Figures 9 and 10 show the MSEs and block-fading CRBs for the (estimated) ML, REML, AML, and LS estimates of \( \text{Re}\{\psi_{3,2}\}, \psi_{3,3}, \psi_{4,4}, \text{sum of all elements of } \psi, \text{and LOS coefficients, as functions of } K \). For the unstructured LOS array response model, the ML estimates of \( x \) outperform the corresponding REML estimates. Interestingly, estimating the LOS Doppler shift does not significantly affect the performances of the ML and REML estimates of the variance components, compare Figs. 7 and 9.

V. CONCLUDING REMARKS

We derived ML and REML methods for estimating the mean and covariance parameters of MIMO fading channels under correlated and independent block-fading scenarios. CRBs were computed for the unknown fading-covariance and line-of-sight parameters. For unitary space-time codes and orthogonal designs in
correlated fading, we obtained closed-form exact and approximate ML estimates of the unknown parameters. We evaluated the performance of the proposed methods via numerical simulations under the block- and continuous-fading scenarios. Simulation results show that the proposed estimators are almost efficient under the block-fading scenario, having mean-square errors close to the corresponding CRBs.

Further research will include: incorporating the proposed estimators into the design of space-time receivers and deriving efficient estimation algorithms and CRBs for the continuous-fading scenario. It is also of interest to develop estimators for the case where the LOS channel response vector follows the multivariate complex Ricean model in [11].

**APPENDIX A. EXPRESSIONS FOR $\Sigma_k(\gamma)^{-1}$ AND THE LOG-LIKELIHOOD FUNCTION**

We derive expressions for $\Sigma_k(\gamma)^{-1}$ and simplify the log-likelihood expression in (3.2). Using the matrix inversion lemma (in e.g. [27, Theorem 18.2.8 at p. 424]), we get:

$$\Sigma_k(\gamma)^{-1} = \sigma^{-2} \left[ I_{n_r N} - Z_k (Z_k^H Z_k)^{-1} Z_k^H \right] + Z_k W_k(\gamma) Z_k^H$$  \hspace{1cm} (A.1)

which further implies

$$\gamma_k^H \Sigma_k(\gamma)^{-1} = A_{LOS,k}^H W_k(\gamma) Z_k^H.$$  \hspace{1cm} (A.2)
Now, the log-likelihood (3.2) can be rewritten as

\[ L(\rho) = -Kn_R N \ln(\pi \sigma^2) - \frac{1}{\sigma^2} \sum_{k=1}^{K} y_k^H \left[ I_{n_R N} - Z_k (Z_k^H Z_k)^{-1} Z_k^H \right] y_k \]

\[ - \sum_{k=1}^{K} (z_k - A_{\text{LOS},k} x)^H W_k(\gamma) (z_k - A_{\text{LOS},k} x) - \sum_{k=1}^{K} \ln |I_{n_R n_T} + (1/\sigma^2) \cdot Z_k^H Z_k| \]

which follows by using (A.1) and the fact that

\[ |\Sigma_k(\gamma)| = (\sigma^2)^{n_R N} \cdot |I_{n_R n_T} + (1/\sigma^2) \cdot Z_k^H Z_k| \]

see (3.1b) and [27, Theorem 18.1.1 at p. 416].

**APPENDIX B. RESTRICTED MAXIMUM LIKELIHOOD**

We derive a REML log-likelihood expression for the measurement model in Section II. Define a vector of error contrasts \( u = B^H y \), where \( B \) is a matrix whose columns span the space orthogonal to the column space of \( T \). Then, the REML log-likelihood is obtained as the log-likelihood function for the error contrasts.
Without loss of generality, we choose \( B^H B = I_{K \times K} \), see [32]. Then, (3.6) follows by using the identities (see [32], and [42, p. 77])

\[
|B^H \Sigma(\gamma) B| = |T^H \Sigma(\gamma)^{-1} T| \cdot |\Sigma(\gamma)| / |T^H T|
\]

\[
B \left[ B^H \Sigma(\gamma) B \right]^{-1} B^H = \Pi(\gamma)
\]

and neglecting terms that do not depend on \( \gamma \). Note that (3.6) can be further simplified by using (A.3):

\[
L_{\text{REML}}(\gamma) = -K n_r \ln \sigma^2 - \sum_{k=1}^{K} \ln |I_{n_r K} + Z_k^H Z_k \psi / \sigma^2| - \frac{1}{\sigma^2} \sum_{k=1}^{K} y_k^H [I_{n_r N} - Z_k (Z_k^H Z_k)^{-1} Z_k^H] y_k
\]

\[
- \ln \left| \sum_{k=1}^{K} A_{\text{LOS},k}^H W_k(\gamma) A_{\text{LOS},k} \right| - \sum_{k=1}^{K} |z_k - A_{\text{LOS},k} \hat{x}(\gamma)|^2 W_k(\gamma) [z_k - A_{\text{LOS},k} \hat{x}(\gamma)]
\]

where \( \hat{x}(\gamma) \) has been defined in (3.3).

**APPENDIX C. ECME ALGORITHMS FOR CORRELATED FADING**

**A. ML Estimation**

We derive the ECME ML algorithm in Section III-A.1. The first conditional maximization (CM) step in (3.7b) follows by substituting the most recent estimate of \( \gamma \) into (3.3), where (3.3) is the ML estimate of \( x \)
that maximizes the observed-data likelihood function for fixed $\gamma$. The second CM step in (3.8a) follows by reparametrizing the variance components using $\Psi' = \Psi / \sigma^2$ and $\sigma^2$ (rather than $\Psi$ and $\sigma^2$), which allows us to find the closed-form solution for the ML estimate of $\sigma^2$ that maximizes the observed-data likelihood function for fixed $\Psi'$ and $x$:

$$\hat{\sigma}^2(x, \Psi') = \frac{1}{KnR_N} \sum_{k=1}^{K} \left\{ y_k^H [I_{nR,N} - Z_k(Z_k^H Z_k)^{-1} Z_k^H] y_k + (z_k - A_{LOS,k} x)^H W'_k(\Psi') (z_k - A_{LOS,k} x) \right\}$$

(C.1)

where

$$W'_k(\Psi') = (Z_k^H Z_k + Z_k^H Z_k \Psi' Z_k^H Z_k)^{-1}.$$  

(C.2)

Equation (C.1) follows by maximizing the (reparametrized) log-likelihood function in (A.3) with $W_k(\gamma)$ replaced by $(1/\sigma^2) \cdot W'_k(\Psi')$. Then, the second CM step for updating the estimate of $\sigma^2$ in (3.8a) is obtained by substituting the most recent estimates of $x$ and $\Psi' = \Psi / \sigma^2$ into (C.1). Finally, we apply the standard EM algorithm to update $\Psi$ by treating $h_{sc,k}$ as the missing data, where $x$ and $\sigma^2$ are fixed. Consequently, $r_k = y_k - \gamma_k x, \; \; k = 1, 2, \ldots, K$ (C.3) are the observed data. If $h_{sc,k}, \; k = 1, 2, \ldots, K$ were known (forming the complete data together with $r_k, \; k = 1, 2, \ldots, K$), we could easily find the complete-data ML estimate of $\Psi$ as follows:

$$\hat{\Psi} = \frac{1}{K} \sum_{k=1}^{K} h_{sc,k} h_{sc,k}^H$$

(C.4)

where $\hat{\Psi}$ is also the natural complete-data sufficient statistic for estimating $\Psi$. Then, the third CM step for updating the estimate of $\Psi$ in (3.8b) follows by computing the conditional expectation of (C.4) given the observed data $r_k, \; k = 1, 2, \ldots, K$. We first find the distribution of the missing data $h_{sc,k}, k = 1, 2, \ldots, K$ conditional on the observed data $r_k, k = 1, 2, \ldots, K$. The joint distribution of $r_k$ and $h_{sc,k}$ is complex Gaussian with mean and covariance

$$E \left\{ \begin{bmatrix} r_k \\ h_{sc,k} \end{bmatrix} \right\} = 0$$

(C.5a)

$$\text{cov} \left\{ \begin{bmatrix} r_k \\ h_{sc,k} \end{bmatrix} \right\} = E \left\{ \begin{bmatrix} r_k \\ h_{sc,k} \end{bmatrix} [\begin{bmatrix} r_k \\ h_{sc,k} \end{bmatrix}]^H \right\} = \begin{bmatrix} \Sigma_k(\gamma) & Z_k \Psi \\ Z_k^H \psi \; & \Psi \end{bmatrix}$$

(C.5b)

and then [20, result 7 at pp. 508–509] implies that $h_{sc,k}$ conditional on $r_k$ are complex Gaussian vectors with means and covariances equal to

$$E[h_{sc,k}|r_k] = \Psi Z_k^H \Sigma_k(\gamma)^{-1} r_k = \Psi Z_k^H Z_k W_k(\gamma) Z_k^H r_k = \Psi Z_k^H Z_k W_k(\gamma)(z_k - A_{LOS,k} x)$$

(C.6a)

$$\text{cov}(h_{sc,k}|r_k) = \psi - \Psi Z_k^H \Sigma_k(\gamma)^{-1} Z_k \psi = \psi - \Psi Z_k^H Z_k W_k(\gamma) Z_k^H Z_k \Psi$$

(C.6b)
where (C.6a) and (C.6b) follow by using (A.1) and (3.4). Now, (3.7c) follows from (C.6a) and the third CM step in (3.8b) is obtained by substituting the most recent estimates of $E[h_{sc,k}|r_k]$ and $\Psi$ into

$$E[\hat{\Psi} - r_k] = \frac{1}{K} \sum_{k=1}^{K} \left( E[h_{sc,k}|r_k] E[h_{sc,k}|r_k]^H + \Psi \left[ I_{n_Rn_T} - Z_k^H Z_k W_k(\gamma) Z_k^H \right] \right). \tag{C.7}$$

### B. REML Estimation

We derive the ECME REML algorithm in Section III-A.2. The CM step for updating the fading covariance matrix in (3.11b) follows by replacing $\Sigma_k(\gamma)^{-1}$ in (C.7) with (see [43, eq. (3.10)] and [34, Sec. 2.3])

$$\Sigma_k(\gamma)^{-1} = \Sigma_k(\gamma)^{-1} T_k^H \Sigma_l(\gamma)^{-1} T_l^{-1} T_k^H \Sigma_k(\gamma)^{-1} = \left( \sigma^2(i) \right)^{-1} \left[ I_{n_Rn_T} - Z_k(\Sigma_k^H Z_k)^{-1} Z_k^H \right]$$

$$+ Z_k W_k(\gamma) Z_k^H - Z_k W_k(\gamma) A_{LOS,k} \left[ \sum_{l=1}^{K} A_{LOS,l}^H W_l(\gamma) A_{LOS,l} \right]^{-1} A_{LOS,k}^H W_k(\gamma) Z_k^H \tag{C.8}$$

and substituting the most recent estimates of $\mathbf{x}$ and $\Psi$. To obtain the right-hand side of (C.8), we used (A.1) and (A.2). The CM step in (3.11a) follows by reparametrizing the variance components using $\sigma^2 = \sigma^2$ and $\sigma^2$. which allows us to find the closed-form solution for the REML estimate of $\sigma^2$ that maximizes the observed-data restricted likelihood function for fixed $\Psi'$ and $\mathbf{x}$:

$$\hat{\sigma^2}(\Psi') = \frac{Kn_RN}{Kn_RN - r} \cdot \hat{\sigma^2} + \frac{1}{Kn_RN - r} \cdot \sum_{k=1}^{K} \left[ z_k - A_{LOS,k} \hat{x}(\Psi') \right]^H W_k(\Psi') \left[ z_k - A_{LOS,k} \hat{x}(\Psi') \right] \tag{C.9}$$

where

$$\hat{x}(\Psi') = \left[ \sum_{k=1}^{K} A_{LOS,k}^H W_k(\Psi') A_{LOS,k} \right]^{-1} \sum_{k=1}^{K} A_{LOS,k}^H W_k(\Psi') z_k \tag{C.10}$$

and $W_k'(\Psi')$ has been defined in (C.2). Then, the CM step for updating the estimate of $\sigma^2$ in (3.11a) is obtained by substituting the most recent estimates of $\hat{x}(\Psi')$ and $\Psi' = \Psi / \sigma^2$ into (C.9).

### APPENDIX D. ML ESTIMATION FOR CORRELATED FADING AND CONSTANT $\Phi_k \Phi_k^H$

We derive the ML estimation algorithm in Section III-A.3, described by equation (3.13) and iteration (3.14)–(3.15). We estimate $\rho$ by iterating between the following two steps:

(i) **(LOS component estimation)** fix $\gamma$ and estimate $\mathbf{x}$ using (3.3);

(ii) **(variance-component estimation)** fix $\mathbf{x}$, compute $r_k$, $k = 1, 2, \ldots, K$ using (C.3), and estimate the variance-component vector $\gamma$ by maximizing the log-likelihood function [see (3.2)]:

$$L(\gamma; \mathbf{x}) = -\sum_{k=1}^{K} \left[ r_k^H \hat{\Sigma}_k(\gamma)^{-1} r_k + \ln |\hat{\Sigma}_k(\gamma)| \right]. \tag{D.1}$$
Note that the above alternating-projection approach is embedded in all the algorithms discussed in this paper. We show that, for constant \( \Phi_k, \Phi_k^H = \Gamma \Phi \) and fixed \( x \), the ML estimates of \( \Psi \) and \( \sigma^2 \) [that maximize (D.1)] are their method-of-moments estimates:

\[
\hat{\sigma}_{\text{ML}}^2 = \frac{1}{Kn_0(N-n_\tau)} \sum_{k=1}^K r_k^H \left[ I_{n_0N} - Z_k (Z_k^H Z_k)^{-1} Z_k^H \right] r_k \tag{D.2a}
\]

\[
= \frac{1}{Kn_0(N-n_\tau)} \sum_{k=1}^K y_k^H \left[ I_{n_0N} - Z_k C^{-1} Z_k^H \right] y_k \tag{D.2b}
\]

\[
\hat{\Psi}_{\text{ML}}(x) = \frac{1}{K} \sum_{k=1}^K \left[ C^{-1} Z_k^H r_k r_k^H Z_k C^{-1} \right] - \hat{\sigma}_{\text{ML}}^2 \cdot C^{-1} \tag{D.2c}
\]

where (D.2b) follows from (D.2a) by using (3.12b) and (A.1). We now prove that the expressions (D.2) indeed maximize (D.1). First, simplify (D.1) using \( C = Z_k^H Z_k \) and (A.3):

\[
L(\gamma; x) \big|_{Z_k^H Z_k = C} = -\frac{1}{\sigma^2} \cdot K n_0(N-n_\tau) \cdot \hat{\sigma}_{\text{ML}}^2 - \text{tr} \left[ \left( \sigma^2 C^{-1} + \Psi \right)^{-1} \sum_{k=1}^K C^{-1} Z_k^H r_k r_k^H Z_k C^{-1} \right]. \tag{D.3}
\]

The above log-likelihood function is the logarithm of a multivariate complex Gaussian pdf which belongs to the multiparameter exponential family of distributions, see [44, ch. 1.6.2]. This fact can be directly verified by inspecting (D.3), which is a linear function of the following natural sufficient statistics: \( \hat{\sigma}_{\text{ML}}^2 \) and \( (1/K) \cdot \sum_{k=1}^K C^{-1} Z_k^H r_k r_k^H Z_k C^{-1} \). Then, [44, Theorem 2.3.1] implies that the moment estimates of \( \sigma^2 \) and \( \Psi \) in (D.2) are also their ML estimates, provided that \( \hat{\Psi}_{\text{ML}} \) in (D.2c) is positive semidefinite.

**APPENDIX E. CRAMÉR-RAO BOUND**

We derive the CRB for the vector of unknown parameters \( \rho \). Using the well-known expression for the Fisher information matrix in e.g. [20, p. 525], the CRB for \( \rho \) is

\[
\text{CRB} = \begin{bmatrix}
\text{CRB}_{xx} & 0 \\
0 & \text{CRB}_{\gamma\gamma}
\end{bmatrix} = \begin{bmatrix}
\mathcal{I}^{-1}_{xx} & 0 \\
0 & \mathcal{I}^{-1}_{\gamma\gamma}
\end{bmatrix} \tag{E.1a}
\]

where \( \text{CRB}_{xx} = \text{CRB}_{[\text{Re}\{x\}^T, \text{Im}\{x\}^T]^T, [\text{Re}\{x\}^T, \text{Im}\{x\}^T]^T} \), \( \mathcal{I}_{xx} = \mathcal{I}_{[\text{Re}\{x\}^T, \text{Im}\{x\}^T]^T, [\text{Re}\{x\}^T, \text{Im}\{x\}^T]^T} = 2 \text{Re} \left\{ \sum_{k=1}^K D_{x,k}^H \Sigma_k(\gamma)^{-1} D_{x,k} \right\} \) \tag{E.1b}

\[
\mathcal{I}_{\gamma\gamma} = \sum_{k=1}^K \text{tr} \left\{ \Sigma_k(\gamma)^{-1} \frac{\partial \Sigma_k(\gamma)}{\partial \gamma_p} \Sigma_k(\gamma)^{-1} \frac{\partial \Sigma_k(\gamma)}{\partial \gamma_q} \right\} \tag{E.1c}
\]

for \( p, q = 1, 2, \ldots, \text{dim}(\gamma) \), and

\[
D_{x,k} = \left[ \frac{\partial (Y_k x)}{\partial (\text{Re}\{x\})^T}, \frac{\partial (Y_k x)}{\partial (\text{Im}\{x\})^T} \right] = [1, j] \otimes Y_k. \tag{E.1d}
\]
Substituting (E.1d) into (E.1b) yields

\[ \mathcal{I}_{x,x} = \text{Re} \left\{ \begin{bmatrix} 1 & j \\ -j & 1 \end{bmatrix} \otimes P_{x,x}(\gamma) \right\} \] (E.2)

where

\[ P_{x,x}(\gamma) = 2 \cdot \sum_{k=1}^{K} \mathcal{T}_{k}^{H} \Sigma_{k}(\gamma)^{-1} \mathcal{T}_{k} = 2 \cdot \sum_{k=1}^{K} A_{\text{LOS},k}^{H} W_{k}(\gamma) A_{\text{LOS},k}. \] (E.3)

It is easy to show that

\[ \text{CRB}_{x,x} = \mathcal{I}_{x,x}^{-1} = \begin{bmatrix} \text{Re}\{P_{x,x}(\gamma)^{-1}\} & \text{Im}\{P_{x,x}(\gamma)^{-1}\} \\ \text{Im}\{P_{x,x}(\gamma)^{-1}\} & \text{Re}\{P_{x,x}(\gamma)^{-1}\} \end{bmatrix}. \] (E.4)

We now use (A.1) to simplify (E.1c). For \( p = 1 \),

\[ [\mathcal{I}_{\gamma,\gamma}]_{1,q} = [\mathcal{I}_{\gamma,\gamma}]_{\sigma_{1},\gamma_{q}} = \sum_{k=1}^{K} \text{tr} \left[ \Sigma_{k}(\gamma)^{-1} \frac{\partial \Sigma_{k}(\gamma)}{\partial \sigma_1^2} \Sigma_{k}(\gamma)^{-1} \frac{\partial \Sigma_{k}(\gamma)}{\partial \gamma_q} \right] = \sum_{k=1}^{K} \text{tr} \left[ \Sigma_{k}(\gamma)^{-2} \frac{\partial \Sigma_{k}(\gamma)}{\partial \gamma_q} \right] = n_{k}(N - n_{\gamma}) K \sigma^{-4} + \sum_{k=1}^{K} \text{tr} \left[ Z_{k}^{H} Z_{k} W_{k}(\gamma) Z_{k}^{H} Z_{k} W_{k}(\gamma) \right], \quad q = 1 \] (E.5)

whereas for \( p, q > 1 \) we have

\[ [\mathcal{I}_{\gamma,\gamma}]_{p,q} = [\mathcal{I}_{\gamma,\gamma}]_{\psi_{p-1},\psi_{q-1}} = \sum_{k=1}^{K} \text{tr} \left[ \Sigma_{k}(\gamma)^{-1} \frac{\partial \Sigma_{k}(\gamma)}{\partial \psi_{p-1}} \Sigma_{k}(\gamma)^{-1} \frac{\partial \Sigma_{k}(\gamma)}{\partial \psi_{q-1}} \right] = \sum_{k=1}^{K} \text{tr} \left[ Z_{k}^{H} Z_{k} W_{k}(\gamma) Z_{k}^{H} Z_{k} W_{k}(\gamma) \right] \frac{\partial \psi}{\partial \psi_{p-1}} \frac{\partial \psi}{\partial \psi_{q-1}}. \] (E.6)

We partition \( \mathcal{I}_{\gamma,\gamma} \) as

\[ \mathcal{I}_{\gamma,\gamma} = \begin{bmatrix} i_{\sigma_{1}^{2},\sigma_{2}} & i_{\psi,\sigma_{2}}^{T} \\ i_{\psi,\sigma_{2}} & \mathcal{I}_{\psi,\psi} \end{bmatrix} \] (E.7)

where \( i_{\sigma_{1}^{2},\sigma_{2}} \) and \( i_{\psi,\sigma_{2}} \) are computed using (E.5), and \( \mathcal{I}_{\psi,\psi} \) is computed using (E.6). We adopt the same block partitioning of \( \text{CRB}_{\gamma,\gamma} = \mathcal{I}_{\gamma,\gamma}^{-1} \). Then,

\[ \text{CRB}_{\psi,\psi} = \frac{\mathcal{I}_{\psi,\psi}^{-1}}{i_{\psi,\sigma_{2}}^{T} i_{\psi,\sigma_{2}} i_{\psi,\sigma_{2}}^{T} \mathcal{I}_{\psi,\psi}^{-1}} \] (E.8a)

\[ \text{CRB}_{\sigma_{1}^{2},\sigma_{2}} = \frac{1}{i_{\psi,\sigma_{2}}^{T} i_{\psi,\sigma_{2}} \mathcal{I}_{\psi,\psi}^{-1} i_{\psi,\sigma_{2}}} \] (E.8b)

which follow by using the formula for the inverse of a partitioned matrix, see e.g. [27, Theorem 8.5.11].

A. CRB for Correlated Fading and Constant \( \Phi_k \Phi_k^{H} \)

We simplify the above CRB expressions for correlated fading and constant \( \Phi_k \Phi_k^{H} = \Gamma_{\phi} \). In this case,

\[ W_{k}(\gamma) = W(\gamma) = (\sigma^2 C + C \Psi C)^{-1} \]
where $C$ has been defined in (3.12b). For the unstructured LOS array response model in (2.4b), (E.4) simplifies to

$$\text{CRB}_{x,x} = \frac{1}{2K} \left[ \begin{array}{c} \text{Re}\{\sigma^2 C + C\psi C\} \\ \text{Im}\{\sigma^2 C + C\psi C\} \\ \text{Re}\{\sigma^2 C + C\psi C\} \end{array} \right].$$  \hspace{1cm} (E.9a)

Under the structured LOS array response model in (2.4c), (E.4) becomes

$$\text{CRB}_{x,x} = \frac{1}{2K} \cdot (a_{1,\text{LOS}}^H \otimes a_{2,\text{LOS}}^H) W(\gamma) (a_{1,\text{LOS}}^H \otimes a_{2,\text{LOS}}^H) \cdot I_2. \hspace{1cm} (E.9b)$$

The equations in (E.5) simplify to

$$i_{\sigma^2,\sigma^2} = K \cdot \{n_0(N - n_0)\sigma^{-4} + \text{tr}[CW(\gamma)CW(\gamma)]\} \hspace{1cm} (E.10a)$$

$$[\mathcal{I}_{\gamma}]^i_{\sigma^2,\sigma^2} = K \cdot \text{tr} \left[ CW(\gamma)CW(\gamma)C \frac{\partial \psi}{\partial \Psi} \right] = K \cdot \left[ CW(\gamma)CW(\gamma)C \right]_{p,p} \hspace{1cm} (E.10b)$$

and, for $p > q$,

$$[\mathcal{I}_{\gamma}]^i_{\sigma^2,\sigma^2} = K \cdot \text{tr} \left[ CW(\gamma)CW(\gamma)C \frac{\partial \psi}{\partial \Psi} \right] = 2K \cdot \text{Re}\left\{ \left[ CW(\gamma)CW(\gamma)C \right]_{p,q} \right\} \hspace{1cm} (E.11a)$$

$$[\mathcal{I}_{\gamma}]^i_{\sigma^2,\sigma^2} = K \cdot \text{tr} \left[ CW(\gamma)CW(\gamma)C \frac{\partial \psi}{\partial \Psi} \right] = 2K \cdot \text{Im}\left\{ \left[ CW(\gamma)CW(\gamma)C \right]_{p,q} \right\} \hspace{1cm} (E.11b)$$

where $\Psi_{p,q}$ denotes the $(p,q)$ element of $\Psi$, for $p, q = 1, 2, \ldots, n_k n_r$. Also, for $p_1 > q_1$ and $p_2 > q_2$, (E.6) becomes

$$[\mathcal{I}_{\gamma}] \text{Re}\{\psi_{p_1,q_1}\}, \text{Re}\{\psi_{p_2,q_2}\} = [\mathcal{I}_{\gamma}] \text{Re}\{\psi_{p_2,q_2}\}, \text{Re}\{\psi_{p_1,q_1}\} = K \cdot \text{tr} \left[ CW(\gamma)C \frac{\partial \psi}{\partial \Psi} \right]$$

$$[\mathcal{I}_{\gamma}] \text{Re}\{\psi_{p_1,q_1}\}, \text{Im}\{\psi_{p_2,q_2}\} = [\mathcal{I}_{\gamma}] \text{Im}\{\psi_{p_2,q_2}\}, \text{Re}\{\psi_{p_1,q_1}\} = K \cdot \text{tr} \left[ CW(\gamma)C \frac{\partial \psi}{\partial \Psi} \right]$$

and, for $p_1 = q_1$ and $p_2 > q_2$,

$$[\mathcal{I}_{\gamma}] \text{Re}\{\psi_{p_1,q_1}\}, \text{Re}\{\psi_{p_2,q_2}\} = K \cdot \text{tr} \left[ CW(\gamma)C \frac{\partial \psi}{\partial \Psi} \right]$$

and, for $p_1 = q_1$ and $p_2 = q_2$,

$$[\mathcal{I}_{\gamma}] \text{Re}\{\psi_{p_1,q_1}\}, \text{Re}\{\psi_{p_2,q_2}\} = K \cdot \text{tr} \left[ CW(\gamma)C \frac{\partial \psi}{\partial \Psi} \right]$$

and, for $p_1 = q_1$ and $p_2 = q_2$,
B. CRB for Independent Fading and $\Phi_k\Phi_k^H = I_{nT}$

For independent fading and unitary space-time codes ($Z_k^HZ_k = I_{n_Rn_T}$), we have:

$$W_k(\gamma) = W(\gamma) = \text{diag}\{ (\sigma^2 + \psi_1)^{-1}, \ldots, (\sigma^2 + \psi_{n_Rn_T})^{-1} \}$$  \hspace{1cm} (E.15)

and the CRB expressions (E.5) and (E.6) simplify to:

$$i_{\sigma^2,\sigma^2} = n_k(N-n_T)K \cdot \sigma^{-4} + K \cdot \sum_{n=1}^{n_Rn_T} (\sigma^2 + \psi_n)^{-2}$$  \hspace{1cm} (E.16a)

$$i_{\psi,\sigma^2} = K \cdot \left[ (\sigma^2 + \psi_1)^{-2}, (\sigma^2 + \psi_2)^{-2}, \ldots, (\sigma^2 + \psi_{n_Rn_T})^{-2} \right]^T$$  \hspace{1cm} (E.16b)

$$I_{\psi,\psi} = K \cdot \text{diag}\{ (\sigma^2 + \psi_1)^{-2}, (\sigma^2 + \psi_2)^{-2}, \ldots, (\sigma^2 + \psi_{n_Rn_T})^{-2} \}$$  \hspace{1cm} (E.16c)

which yields (3.23) after applying (E.8). The CRB expressions for the LOS coefficients under the unstructured and structured LOS array response models follow by substituting $C = I_{n_Rn_T}$, $\Psi = \text{diag}(\psi_1, \psi_2, \ldots, \psi_{n_Rn_T})$ and (E.15) into (E.9a) and (E.9b).

ACKNOWLEDGMENT

The authors are grateful to the anonymous reviewers for their helpful comments.

LIST OF TABLES

1 Percentages of trials in which the alternating-projection and closed-form estimators for the structured and unstructured LOS array response models in (3.15) and (3.16b) were not positive semidefinite, as functions of $K$. .......................... 15
Unstructured LOS array model

Structured LOS array model

MSEs of $\Psi$ estimates

Number of coherent intervals $K$

- $\phi$: REML
- $\rightarrow$: ML
- $\longrightarrow$: CRB

$\psi$, $\psi_{33}$, $\psi_{44}$, $\psi_{32}$, $\text{Re}(\psi_{32})$
Number of coherent intervals $K$

MSEs of unstructured LOS $x$

MSEs of structured LOS $x$

- REML
- ML
- CRB
- LS
- AML
- REML
- ML
- CRB

Number of coherent intervals $K$
Number of coherent intervals $K$

Bias of $\Psi$ estimates

Unstructured LOS array model

Structured LOS array model
Number of coherent intervals $K$

MSEs of Doppler shift estimate
Unstructured LOS array model

Structured LOS array model

MSEs of $\Psi$ estimate

Number of coherent intervals $K$

$\Psi_4$
$\Psi_3$
$\Psi_2$
$\Psi_1$

REML
ML
CRB
Number of coherent intervals $K$

MSEs of unstructured LOS $x$

- REML
- ML
- CRB

MSEs of structured LOS $x$

- LS
- AML
- REML
- ML
- CRB
Unstructured LOS array model

Structured LOS array model

Number of coherent intervals $K$

MSEs of $\Psi$ estimates

REML
ML
Block–fading CRB

$\Psi_{33}$
$\Psi_{44}$
$\text{Re}(\Psi_{32})$
$\text{Re}(\Psi_{32})$
$\Psi_{33}$
Number of coherent intervals $K$

MSEs of unstructured LOS $x$

- REML
- ML
- Block-fading CRB

MSEs of structured LOS $x$

- LS
- AML
- REML
- ML
- Block-fading CRB

Number of coherent intervals $K$
Unstructured LOS array model

Structured LOS array model

MSEs of $\Psi$ estimates

- REML
- ML
- Block-fading CRB

MSEs of $\Psi$ estimates

$\Psi$, $\Psi_{33}$, $\Psi_{44}$, $\Psi_{32}$, $\Re\{\Psi_{32}\}$

Number of coherent intervals $K$
