Enhanced moments of Eu in single crystals of the metallic helical antiferromagnet EuCo2-yAs2

Abstract
The compound EuCo2-yAs2 with the tetragonal ThCr2Si2 structure is known to contain Eu+2 ions with spin $S = 7/2$ that order below a temperature $T_N$ approximate to 47 K into an antiferromagnetic (AFM) proper helical structure with the ordered moments aligned in the tetragonal ab plane, perpendicular to the helix axis along the c axis, with no contribution from the Co atoms. Here we carry out a detailed investigation of the properties of single crystals. We consistently find about 5% vacancies on the Co site from energy-dispersive x-ray analysis and x-ray diffraction refinements. Enhanced ordered and effective moments of the Eu spins are found in most of our crystals. Electronic structure calculations indicate that the enhanced moments arise from polarization of the d bands, as occurs in ferromagnetic Gd metal. Electrical resistivity measurements indicate metallic behavior. The low-field in-plane magnetic susceptibilities $\chi(\text{ab})$ ($T < T_N$) for several crystals are reported that are fitted well by unified molecular field theory (MFT), and the Eu-Eu exchange interactions $J(\text{ij})$ are extracted from the fits. High-field magnetization $M$ data for magnetic fields $H$ parallel to ab reveal what appears to be a first-order spin-flop transition followed at higher field by a second-order metamagnetic transition of unknown origin, and then by another second-order transition to the paramagnetic (PM) state. For $H$ parallel to c, the magnetization shows only a second-order transition from the canted AFM to the PM state, as expected. The critical fields for the AFM to PM transition are in approximate agreement with the predictions of MFT. Heat capacity $C_p$ measurements in zero and high $H$ are reported. Phase diagrams for $H$ parallel to c and $H$ parallel to ab versus $T$ are constructed from the high-field $M(H, T)$ and $C_p(H, T)$ measurements. The magnetic part $C_{\text{mag}}(T, H = 0)$ of $C_p(T, H = 0)$ is extracted and is fitted rather well below $T_N$ by MFT, although dynamic short-range AFM order is apparent in $C_{\text{mag}}(T)$ up to about 70 K, where the molar entropy attains its high-T limit of $R \ln 8$.

I. INTRODUCTION

Many studies of iron-based layered pnictides and chalcogenides have appeared due to their unique lattice, electronic, magnetic, and superconducting properties [1–9]. An important family of these materials consists of doped and undoped compounds AIr$_2$As$_2$ ($A =$ Ca, Sr, Ba, Eu) with the body-centered tetragonal ThCr$_2$Si$_2$ structure with space group $I4/mmm$ (122-type compounds). Searches for novel physical properties in various 122-type compounds with other transition metals replacing Fe have been carried out, such as for Mn [10–19] and Cr [20–27].

Here we are concerned with AlCo$_2$As$_2$ and AlCo$_2$P$_2$ compounds (Co122 systems) with the ThCr$_2$Si$_2$ structure that have also attracted much interest due to their rich magnetic behaviors, where the electronic states of the CoAs and CoP layers are sensitive to the crystal structure. By forming As–As and P–P bonds along the $c$ axis, their crystal structures can collapse along this axis, resulting in the so-called collapsed-tetragonal (cT) structure which is to be distinguished from the uncollapsed-tetragonal (ucT) structure. In contrast to the Fe122 compounds that exhibit a magnetic to nonmagnetic transition under pressure coincident with a ucT to cT transition, the Co-based compounds behave in the opposite manner, with the ambient-pressure ucT compounds being paramagnetic and the cT compounds exhibiting magnetic ordering [28]. For example, CaCo$_2$As$_2$ has a cT structure at ambient pressure and manifests itinerant A-type antiferromagnetic (AFM) ordering with the ordered moments aligned along the $c$ axis [29,30], whereas the 122-type SrCo$_2$As$_2$ and BaCo$_2$As$_2$ compounds have ucT structures with no long-range magnetic ordering [31,32]. Inelastic neutron scattering and NMR studies on SrCo$_2$As$_2$ have revealed strong stripe-type AFM correlations at high energies whereas NMR measurements reveal strong FM correlations at low energies [33,34]. On the other hand, the system SrCo$_2$(Ge$_{1-x}$P$_x$)$_2$ develops weak itinerant ferromagnetism during the course of the dimer breaking, and a quantum critical point (QCP) is observed at the onset of the FM phase, although both SrCo$_2$P$_2$ (ucT) and SrCo$_2$Ge$_2$ (cT) are paramagnetic (PM) [35]. From first-principles calculations, it was shown that the degree of As–As covalent bonding in CaFe$_2$As$_2$ and the magnitude of the spin on the Fe atoms are...
inversely related [36,37]. Similarly, the magnetic properties of the cobalt pnictides were correlated with changes in the formal Co charge as determined by the estimated degree of P-P covalent bonding along the c axis [38].

EuCo2P2 is an interesting uCt compound in the Co122 family. It shows AFM ordering of the Eu2+ spins S = 7/2 below TN ≈ 66 K [39]. Neutron-diffraction studies demonstrated that the AFM structure is a planar helix with the Eu ordered moments aligned in the ab plane of the tetragonal structure, and with the helix axis being the c axis [40]. This compound shows a pressure-induced first-order uCt to cT transition at ≈3 GPa [41] associated with the valence change of Eu from Eu2+ to nonmagnetic Eu+ together with the emergence of itinerant 3d magnetism in the Co sublattice, which orders AFM at TN = 260 K [42]. We showed that EuCo2P2 is a textbook example of a noncollinear helical antiferromagnet for which the thermodynamic properties in the antiferromagnetic state are well described by our unified molecular field theory (MFT) [43].

EuCo2As2 also has the uCt 122-type structure and hence is isostructural and isoelectronic to EuCo2P2 [44,45]. It exhibits AFM ordering of the Eu2+ spins -S=7/2 at TN = 47 K [46,47]. Neutron-diffraction measurements showed that the AFM structure is the same coplanar helical structure as in EuCo2P2, with no participation by Co moments [44]. Here the reported helix propagation vector is k = (0,0,0.79)/(2π/c) [44], very similar to that of EuCo2P2 which is k = (0,0,0.85)/(2π/c) [40]. The c/a ratios of EuCo2P2 (3.01) and EuCo2As2 (2.93) are also similar and both indicate a uCt structure. High-pressure measurements on EuCo2As2 showed a continuous tetragonal to collapsed tetragonal crossover at a pressure p ≈ 5 GPa [48] and a change in the associated valence state of Eu, achieving the average oxidation state of Eu+2.25 at 12.6 GPa. As a result, ferromagnetic (FM) ordering arises from both Eu and Co moments with a Curie temperature TC = 125 K, which is confirmed by x-ray magnetic circular dichroism measurements and electronic structure calculations.

One reason for carrying out the present detailed study of EuCo2−xAs2 is that the reported effective magnetic moment in the paramagnetic (PM) state μeff ≈ 8.22 μB/Eu is significantly larger than the value of μeff = 7.94 μB expected for Eu2+ [45] (see also Table I below). Normally, the effective and ordered moments of Eu+2 and Gd+3 are rather robust due to the spin-only electronic configurations of these S = 7/2 ions (orbital angular momentum L = 0). The questions we wanted to address were how repeatable the large μeff is in different samples, how it comes about, and to see if it correlates with other properties of the material. In addition, we wanted to test our unified molecular field theory to fit the magnetic and thermal properties below TN for another helical AFM to complement our earlier studies of EuCo2P2 [43].

We grew single crystals of EuCo2−xAs2 with two different fluxes and report their properties. We find that there is a rather large range of μeff values as well as of low-temperature ordered (saturation) moments μsat of the Eu spins in different crystals. As in CaCo2−xAs2 [29,30], we also find a significant (~5%) vacancy concentration on the Co sites in most of our EuCo2−xAs2 crystals.

The experimental details are given in Sec. II. In Sec. III the crystal structure and composition analyses are presented for

### Table I.
The compositions of our six EuCo2−xAs2 single crystals, together with the error bars on the Co concentrations obtained from the combined EDX and XRD data, in comparison with previous studies on this compound. Also listed are crystallographic data for the single crystals at room temperature, including the fractional c-axis position zAs of the As site, the tetragonal lattice parameters a and c, the unit-cell volume Vcell, containing two formula units of EuCo2−xAs2, and the c/a ratio. The AFM ordering temperature TN is also shown. The listed values of the effective moment μeff obtained from the Curie constant in the Curie-Weiss law are averages of the c-axis and ab-plane values (see Table III below). Most values are larger than the value obtained for S = 7/2 and g = 2, which is μeff = 7.94 μB/Eu. The present work is denoted by PW. Data from the literature are also shown.

ENHANCED MOMENTS OF Eu IN SINGLE CRYSTALS OF EuCo2As2

PHYSICAL REVIEW B 97, 144403 (2018)

six crystals for which the physical properties are later studied in detail. Our magnetic susceptibility $\chi$ versus temperature $T$ data and magnetization versus field $M(H)$ isotherms for the crystals are presented in Sec. IV, where we find enhancements in both $\mu_{eff}$ and $\mu_{sat}$ compared to expectation for Eu$^{2+}$ spins with $S = \frac{7}{2}$ and spectroscopic splitting factor $g = 2$. We also obtain an estimate of the amount of anisotropy in the system and fit the in-plane $\chi_{ab}(T)$ at temperatures $T$ less than the AFM ordering temperature $T_N$ by MFT.

Our zero-field and high-field heat capacity $C_p(H, T)$ measurements are presented in Sec. V, where the magnetic contribution $C_{mag}(T, H = 0)$ is extracted and found to agree rather well with the prediction of MFT for $S = \frac{7}{2}$ at $T \leq T_N$. However, dynamic short-range AFM ordering is found from $T_N \approx 42$ K up to about 70 K, which is not accounted for by MFT. The molar magnetic entropy $S_{mag}$ is found to agree with expectation for Eu spins $S = \frac{7}{2}$ at high $T \gtrsim 70$ K. $R \ln(2S + 1)$, where $R$ is the molar gas constant. From the high-field $C_p(H, T)$ we extract $T_N(H)$ for $H \parallel c$ and obtain a good fit by MFT. Using the high-field data from the $M(H)$ and $C_p(T)$ measurements, the phase diagrams in the $H \parallel c$ and $H \parallel ab$ versus $T$ planes are constructed for two different crystals in Sec. VI. Electrical resistivity data for currents in the $ab$ plane are presented in Sec. VII. Together with an analysis of these data in terms of the generic electron-electron scattering model at low $T$ and the Bloch-Grüneisen, parallel-resistor, and $s$-d scattering models at higher $T$.

Our total-energy and electronic structure calculations are presented in Sec. VIII. We find that the Eu spins ferromagnetically polarize the spins of the electrons deriving from the Co 3$d$ t$_{2g}$ states near the Fermi level by an amount consistent with the observed enhancement of the Eu moments. The calculations also indicate that the Co atoms make no contribution to the helical AFM structure, again consistent with experiment. In Sec. IX we extract the Heisenberg exchange interactions $J_{ij}$ from the previously presented MFT fit to the $\chi_{ab}(T \leq T_N)$ data. A summary of our results is given in Sec. X.

II. EXPERIMENTAL DETAILS

Single crystals of EuCo$_2$As$_2$ were grown in Sn flux and CoAs flux. The purity and sources of the elements used were Eu (Ames Lab), and Co (99.999%), As (99.999%), and Sn (99.9999%) from Alfa Aesar. For some crystal growths, the Co powder was additionally heated under a flow of H$_2$ gas (99.9999%) from Alfa Aesar. For some crystal growths, the Co powder was additionally heated under a flow of H$_2$ gas (99.9999%) from Alfa Aesar. For some crystal growths, the Co powder was additionally heated under a flow of H$_2$ gas (99.9999%) from Alfa Aesar. For some crystal growths, the Co powder was additionally heated under a flow of H$_2$ gas (99.9999%) from Alfa Aesar. For some crystal growths, the Co powder was additionally heated under a flow of H$_2$ gas (99.9999%) from Alfa Aesar. For some crystal growths, the Co powder was additionally heated under a flow of H$_2$ gas (99.9999%) from Alfa Aesar. For some crystal growths, the Co powder was additionally heated under a flow of H$_2$ gas (99.9999%) from Alfa Aesar. For some crystal growths, the Co powder was additionally heated under a flow of H$_2$ gas (99.9999%) from Alfa Aesar.

For Sn-flux growth, the starting materials were mixed in the molar ratio Eu:Co:As:Sn = 1.05:2:2:15. Excess Eu was required in order to obtain crystals without impurity phases occluded on or embedded within the crystals. The mixture was placed in an alumina crucible and then sealed in a quartz tube under high-purity argon gas. After prereacting the elements at 600 °C for 6 h, the mixtures were placed in a box furnace and heated to 1050 °C at a rate of 50 °C/h, held there for 20 h, and then cooled to 600 °C at a rate of 4 °C/h. At this temperature, the molten Sn flux was decanted using a centrifuge. Shiny platelike crystals of area 4–40 mm$^2$ by $\approx$ 0.4 mm thick were obtained.

For CoAs-flux growth, a mixture of Eu metal and prereacted CoAs powder taken in the molar ratio Eu:CoAs = 1:4 was placed in an alumina crucible and then sealed in a quartz tube under high-purity argon gas. The tube assembly was placed in a box furnace and heated to 1300 °C at a rate of 50 °C/h, held there for 15 h, and then cooled to 1180 °C at a rate of 6 °C/h. At this temperature, the excess CoAs flux was decanted using a centrifuge. For this crystal-growth method shiny platelike crystals of size 4–40 mm$^2$ by 0.3–0.4 mm thick were obtained.

The phase purity and chemical composition of the EuCo$_2$As$_2$ crystals were checked using an energy-dispersive x-ray (EDX) semiquantitative chemical analysis attachment to a JEOL scanning electron microscope (SEM). SEM scans were taken on cleaved surfaces of the crystals which verified the single-phase nature of the crystals. The compositions of each side of a platelike crystal were measured at six or seven positions on each face, and the results were averaged. The EDX composition analysis revealed the presence of vacancies on the Co site and an absence of Sn incorporated into the bulk of the crystals. The EDX data also showed no evidence for oxygen in any of the crystals. We selected six crystals having different Co-site occupancies for further investigations.

Single-crystal x-ray diffraction (XRD) measurements were performed at room temperature on a Bruker D8 Venture diffractometer operating at 50 kV and 1 mA equipped with a Photon 100 CMOS detector, a flat graphite monochromator and a Mo Kα I$_\alpha$S microfocus source ($\lambda = 0.71073$ Å). The raw frame data were collected using the Bruker APEX3 program [50], while the frames were integrated with the Bruker SAINT software package [51] using a narrow-frame algorithm for integration of the data and were corrected for absorption effects using the multiscan method (SADABS) [52]. The occupancies of the Co atomic sites were refined assuming random occupancy of the Co sites and assuming complete occupancy of the Eu and As sites. The atomic thermal factors were refined anisotropically. Initial models of the crystal structures were first obtained with the program SHELXT-2014 [53] and refined using the program SHELXL-2014 [54] within the APEX3 software package.

Magnetization data were obtained using a Quantum Design, Inc., magnetic properties measurement system (MPMS) and a vibrating sample magnetometer in a Quantum Design, Inc., physical properties measurement system (PPMS) for high-field measurements up to 14 T, where 1 T $\equiv 10^4$ Oe. The PPMS was used for $C_p(T)$ and $\rho(T)$ measurements. The $C_p(T)$ was measured by the relaxation method and the $\rho(T)$ using the standard four-probe ac technique.

III. CRYSTAL STRUCTURES AND COMPOSITIONS

The chemical compositions and crystallographic data are presented in Table I for six crystals of EuCo$_2$. As$_2$ grown under different conditions with different Co vacancy concentrations as determined above, which are labeled #1 to #6, respectively. The chemical compositions obtained from the EDX and single-crystal XRD analyses for these six crystals of EuCo$_2$As$_2$ are also listed in Table I in comparison with the previous studies on this compound [44–46,48]. The physical
property measurements reported in this paper were carried out on these six crystals.

IV. MAGNETIC SUSCEPTIBILITY AND HIGH-FIELD MAGNETIZATION

A. Magnetic susceptibility

Figures 1 and 2 display the zero-field-cooled (ZFC) magnetic susceptibility $\chi \equiv M/H$ of Sn-flux-grown crystals and CoAs-flux-grown crystals, respectively, as a function of temperature $T$ measured in a magnetic field $H = 0.1$ T applied in the $ab$ plane ($\chi_{ab}$) and along the $c$ axis ($\chi_c$). Insets: the respective derivative $d(\chi_{ab}/dT)$ versus $T$.

FIG. 1. Zero-field-cooled (ZFC) magnetic susceptibility $\chi \equiv M/H$ of Sn-flux-grown crystals (a) #1 EuCo$_{1.99(2)}$As$_2$ and (b) #2 EuCo$_{1.99(2)}$As$_2$ as a function of the temperature of the maximum slope of $\chi_T$ versus $T$ for the easy axis direction $\parallel z$. Insets: the derivative $d(\chi_{ab}/dT)$ versus $T$. The $N$ values shown in the insets of Figs. 1 and 2 as well as in Table I and in Table III below. From Table I one sees that the $T_N$ values correlate with the crystallographic $c/a$ ratio and with the flux used to grow the crystals, not with the Co-site occupancy. The $T_N$ values from previous reports on EuCo$_{2-x}$As$_2$ are also listed in Table I [44,46,47].

For all four crystals, from the main panels in Figs. 1 and 2 one sees that $\chi_{ab} > \chi_c$ in the paramagnetic regime ($T > T_N$), indicating the presence of a magnetic anisotropy favoring the $ab$ plane. This is consistent with the data for $T \ll T_N$ which indicates that the crystallographic $ab$ plane is an AFM easy plane. For $T < T_N$, one sees that $\chi_c$ is nearly independent of $T$, consistent with the molecular-field theory prediction for a field perpendicular to the ordering axis or plane of a Heisenberg AFM [56,57]. Magnetocrystalline anisotropy determines the ordering axis or plane such as for a Heisenberg AFM with dipolar [58], uniaxial single-ion $DS^2_z$ [59], and classical field [60] anisotropies. The observation that $\chi_{ab}$ for $T \to 0$ is a large
fraction of $\chi_c(T \to 0)$ indicates that EuCo$_{2-y}$As$_2$ is either a collinear AFM with multiple domains in the $ab$ plane or a coplanar noncollinear $ab$-plane AFM structure. The previous neutron-diffraction study on EuCo$_2$As$_2$ indeed showed an incommensurate AFM helical structure in which Eu spins are aligned ferromagnetically within the $ab$ plane, where the helix axis is the $c$ axis with an AFM propagation vector of $k = (0,0,0.79)\pi/c$ where $c$ is the tetragonal $c$-axis lattice parameter [44]. An incommensurate helical spin structure with almost the same propagation vector was found in the isostructural compound EuCo$_2$P$_2$ [40,43].

The inverse susceptibility $\chi^{-1}(T)$ measured in $H = 0.1$ T applied along the $c$ axis ($\chi^{-1}_c$) and in the $ab$ plane ($\chi^{-1}_{ab}$) for Sn-flux- and CoAs-flux-grown crystals are shown in Figs. 3 and 4, respectively. As one can see from the figures, the $\chi^{-1}(T)$ plots are slightly curved. One can fit this curvature by including a $T$-independent term $\chi_0$ in addition to the Curie-Weiss law, giving a so-called modified Curie-Weiss law

$$\chi_\alpha = \chi_0 + \frac{C_\alpha}{T - \theta_\alpha} \quad (\alpha = ab, c), \quad (1a)$$

where $\chi_0$ is an isotropic temperature-independent term given by

$$\chi_0 = \chi_{\text{dia}} + \chi_{\text{para}} = \chi_{\text{core}} + \chi_{\text{Landau}} + \chi_{\text{Pauli}}, \quad (1b)$$

which is comprised of the diamagnetic (negative) atomic core ($\chi_{\text{core}}$) and conduction-electron orbital Landau ($\chi_{\text{Landau}}$) contributions and the paramagnetic (positive) contribution from the Pauli spin susceptibility ($\chi_{\text{Pauli}}$) of the conduction electrons and/or holes. The Curie constant per mole of spins is
and \( \mu \) crystal are the Curie constant, \( C \), Weiss temperature \( \theta_p \), and effective moment \( \mu_{\text{eff}} \) obtained from \( C \) using Eq. (1d). For reference, for a spin \( S = \frac{7}{2} \) with \( g = 2 \), Eqs. (1a) and (1e) yield \( C = 7.878 {\text{cm}^3}\text{K/mol Eu} \) and \( \mu_{\text{eff}} = 7.937 \mu_B/\text{Eu} \).

\( ^a \text{Grown in Sn flux.} \)
\( ^b \text{Grown in Sn flux with H}_2\text{-treated Co powder.} \)
\( ^c \text{Grown in CoAs flux with H}_2\text{-treated Co powder.} \)
\( ^d \text{Grown in CoAs flux.} \)

given by [61]

\[
C = \frac{N_A \mu_B^2 S(S + 1)}{3k_B} = \frac{N_A \mu_{\text{eff}}^2 \mu_B^2}{3k_B}, \quad (1c)
\]

where \( N_A \) is Avogadro’s number and \( \mu_{\text{eff}} \) is the effective moment of a spin in units of Bohr magnetons. From Eq. (1c) one obtains

\[
\mu_{\text{eff}} = g \sqrt{S(S + 1)} \approx \sqrt{3k_B C / N_A \mu_B^2}, \quad (1d)
\]

Inserting the Gaussian cgs values of the fundamental constants into Eq. (1d) gives

\[
\mu_{\text{eff}} \approx \sqrt{7.99 \times 684 C} \approx \sqrt{8 C}. \quad (1e)
\]

As a baseline, we fitted the \( \chi_p(T) \) data by Eq. (1a) from 100 to 300 K with \( \chi_0 = 0 \) for each of five of our crystals for each of the two field directions, and the fitted \( C \) and \( \theta_p \) values are shown in Table II together with \( \mu_{\text{eff}} \) calculated from \( C \) using Eq. (1e). One sees that the values of \( \mu_{\text{eff}} \) are 4% to 7% larger than the value for \( S = \frac{7}{2} \) with \( g = 2 \) given in the table caption, not including the data for outlier crystal #3. These differences are outside the experimental error of \( \sim 1\% \). Our enhanced values of \( \mu_{\text{eff}} \) are in qualitative agreement with the previous value in Table I reported in Ref. [47]. The positive values of \( \theta_p \) indicate a net FM exchange interaction between the Eu\(^{2+} \) spins-7\(^2\). The value of \( \theta_p \) obtained from a fit of experimental \( \chi_p(T) \) data in the paramagnetic regime at \( T > T_N \) by Eq. (1a) can be affected by crystal-shape (demagnetization) effects if \( \chi_p \) is large such as for compounds containing high concentrations of large-spin species such as Eu\(^{2+} \) with spin \( S = \frac{7}{2} \) in EuCo\(_{2-\gamma}\)As\(_2\). From the treatment in Ref. [58], for \( \chi_0 = 0 \) these affect the Weiss temperature according to

\[
\theta_p = \theta_{p0} - \frac{4\pi C_A N_{da}}{V_M}, \quad (2a)
\]

where \( \theta_{p0} \) is the fitted value as above, \( C_A \) is the Curie constant per mole of magnetic atoms, \( \theta_{p0} \) is the Weiss temperature that would have been obtained in the absence of demagnetization effects, \( N_{da} \) is the magnetometric demagnetization factor in SI units (0 \( \leq N_{da} \leq 1 \)) of a crystal with the applied field in the \( \alpha \) direction, and \( V_M \) is the volume per mole of magnetic atoms in the crystal. For spins-7\(^2\) with \( g = 2 \) one has isotropic \( C_A = 7.88 {\text{cm}^3}\text{K/mol} \) and using the crystal data in Table I one obtains \( V_M \approx 53 {\text{cm}^3/mol} \) for EuCo\(_{2-\gamma}\)As\(_2\). Then, for EuCo\(_{2-\gamma}\)As\(_2\), Eq. (2a) gives

\[
\theta_p = \theta_{p0} - (1.9 K)N_{da}. \quad (2b)
\]

Since 0 \( \leq N_{da} \leq 1 \), a fitted positive value of \( \theta_p \) in Table II can thus be decreased by up to 1.9 K due to demagnetization effects, which is a maximum of \( \approx 10\% \) of the \( \theta_{p0} \) values.

The data for \( C \), \( \mu_{\text{eff}} \), and \( \theta_p \) for crystal #3 in Table II are outliers. We infer that these erroneous values arise from the contribution of a small amount of a ferromagnetic impurity to the magnetization. In particular, including a \( \chi_0 \) in the fits below yields a positive value that includes the FM impurity contribution and leads to \( C \), \( \mu_{\text{eff}} \), and \( \theta_p \) values in better alignment with those for the other four crystals. From the value of \( \chi_0 \) obtained for crystal #3 below we estimate the contribution of the FM impurity to the magnetization of the crystal in the measuring field of 0.1 T to be \( \sim 5 \times 10^{-4} \mu_B/\text{f.u.} \).

Next, we included \( \chi_0 \) in the fits and the three fitting parameters are listed in Table III along with the previous reports for this compound. Most of the \( \chi_0 \) values are strongly negative. The fits are shown as the solid curves in Figs. 3 and 4.

Now we obtain an estimate of \( \chi_0 \) expected for EuCo\(_{2-\gamma}\)As\(_2\). EuCo\(_{2-\gamma}\)As\(_2\) is not an ionic compound, so we do not use the ionic values [62] for the \( \chi^{\text{core}} \) contributions. Instead, we use the atomic core contributions tabulated in Table 2.1 of Ref. [63], which are given per mole of atoms as

\[
\chi^{\text{core}}(\text{Eu}) = -7.0 \times 10^{-5} {\text{cm}^3/mol}, \quad (3a)
\]

\[
\chi^{\text{core}}(\text{Co}) = -3.1 \times 10^{-5} {\text{cm}^3/mol}, \quad (3b)
\]

\[
\chi^{\text{core}}(\text{As}) = -3.3 \times 10^{-5} {\text{cm}^3/mol}, \quad (3c)
\]

yielding the core susceptibility per mole of EuCo\(_{2-\gamma}\)As\(_2\) as

\[
\chi^{\text{core}}(\text{EuCo}_{2-\gamma}\text{As}_2) = -1.98 \times 10^{-4} {\text{cm}^3/mol}. \quad (3d)
\]

Assuming the \( g \) factor of the conduction carriers is \( g = 2 \), the Pauli spin susceptibility of the conduction carriers in cgs units is given by

\[
\chi^{\text{Pauli}} \left[ \frac{{\text{cm}^3}}{{\text{mol}}} \right] = (3.233 \times 10^{-5} g)\langle E_F \rangle \left[ \frac{\text{states}}{\text{eV f.u.}} \right]. \quad (4)
\]

where f.u. means the formula unit of EuCo\(_{2-\gamma}\)As\(_2\) and the density of states at the Fermi energy \( g \langle E_F \rangle \) is for both spin directions, i.e., taking into account the Zeeman degeneracy of the conduction carriers. Taking \( g \langle E_F \rangle \approx 7 \text{ states/eV f.u.} \) obtained from the \( C_p(T) \) measurements in Table V below, one
TABLE III. Parameters obtained from modified Curie-Weiss fits of the magnetic susceptibility data between 100 and 300 K for EuCo2−xAs2, where \( T_N \) is the Néel temperature, \( \chi_0 \) is the \( T \)-independent contribution to the susceptibility, \( C_\alpha \) is the molar Curie constant for fields in the \( \alpha = ab, c \) direction, \( \mu_{\text{eff}} \) is the effective moment, \( \theta_p \) is the Weiss temperature, \( \theta_{\text{pave}} \) is the spherical average of \( \theta_p \), \( J_{sf} \) is the exchange interaction between a local \( f \)-electron atom and the \( s \) conduction electrons. For reference, the effective moment for Eu1+ with \( g = 2 \) and \( S = \frac{7}{2} \) is \( \mu_{\text{eff}} = g \sqrt{\chi(S+1)} \mu_B = 7.94 \mu_B \). The quantity \( f_j \) is defined as \( f_j = \theta_{\text{pave}}/T_N \). PW means present work and N/A means not applicable.

\( ^{a} \)Grown in Sn flux.
\( ^{b} \)Grown in Sn flux with H₂-treated Co powder.
\( ^{c} \)Grown in CoAs flux with H₂-treated Co powder.
\( ^{d} \)Grown in CoAs flux.
\( ^{e} \)Grown in Bi flux.
\( ^{f} \)The data were sent to us by the authors and we fitted them by \( \chi = C/(T - \theta_p) \) from 100 to 300 K.
\( ^{g} \)Polycrystalline sample.

obtains

\[
\chi^{\text{Pauli}} \approx 2.3 \times 10^{-4} \text{ cm}^3 \text{ mol}^{-1} \quad (5)
\]

Then taking into account the Landau diamagnetism of the conduction carriers assuming a free-carrier gas gives the \( T \)-independent contribution to \( \chi \) according to Eq. (1b) as

\[
\chi_0 = \chi^{\text{core}} + \frac{2}{3} \chi^{\text{Pauli}} \approx -4.7 \times 10^{-5} \text{ cm}^3 \text{ mol}^{-1} \quad (6)
\]

This value is much smaller in magnitude than the \( \chi_0 \) values listed for crystals \#1, \#2, \#4, and \#5 in Table III, suggesting that these large negative values may instead be reflections of \( T \)-dependent Curie constants and Weiss temperatures, a possibility examined next.

In order to investigate the possible \( T \) dependencies of \( C_\alpha \) and \( \theta_p \), we again set \( \chi_0 = 0 \). We obtained a spline fit to \( \chi_\alpha(T) \) from 70 to 300 K, and from that we obtained the temperature derivative \( \chi'_\alpha(T) \). Then one has the two simultaneous equations

\[
\chi_\alpha(T) = \frac{C_\alpha}{T - \theta_p}, \quad (7a)
\]

\[
\chi'_\alpha(T) = -\frac{C_\alpha}{(T - \theta_p)^2}, \quad (7b)
\]

from which \( C_\alpha \) and \( \theta_p \) were solved for at each \( T \). The results are shown in Fig. 5 for Sn-flux-grown crystals \#1 EuCo1.90(1)As2 and \#2 EuCo1.99(4)As2 and for CoAs-flux-grown crystal \#4 EuCo1.90(2)As2. One sees smooth variations in \( C_\alpha \) and \( \theta_p \) versus \( T \) for each crystal, where \( C_\alpha \) increases and \( \theta_p \) decreases monotonically with decreasing \( T \) for each of the three crystals. This behavior of \( C_\alpha \) might be expected if the Eu spins polarize the conduction electrons since the polarization might be expected to increase with decreasing \( T \).

The possibility of conduction-electron polarization due to hybridization with the Eu \( 4f \) states can occur. As a result, the observed effective moment for an \( s \)-state Eu spin–\( \frac{7}{2} \) is given by [64]

\[
\mu_{\text{eff}}^{\text{obs}} = \mu_{\text{eff}} \left[ 1 + \frac{2}{g} \rho_0(E_F)J_{sf} \right]. \quad (8)
\]

Here we take \( g = 2 \), \( \rho_0(E_F) \) is the density of states per atom at the Fermi level for one spin direction, and \( J_{sf} \) is the effective conduction electron-\( 4f \) exchange interaction due to either direct exchange (positive) or \( sf \) mixing (negative). The values of \( \rho_0(E_F)J_{sf} \) estimated from the effective moments of EuCo2−xAs2 compounds and Eq. (8) are given in the next-to-last column of Table III. The positive sign of the quantity suggests that the \( sf \) interaction mechanism in these compounds could be due to direct exchange. These interactions are expected to be affected by the change in lattice parameters \( a \) and \( c \), and the overall unit-cell volume \( V_{\text{cell}} \). Therefore, the excess Eu moment is related to the contribution of the non-\( 4f \) electrons, which here is mainly from Co \( d \) electrons (see below). This gives rise to dressing of a bare rare-earth spin with a conduction electron spin cloud which for EuCo2−xAs2 would
add a portion of conduction-electron spin magnetization to the free Eu$^{2+}$ moment. These effects are related to the indirect RKKY (Ruderman-Kittel-Kasuya-Yosida) exchange interaction [65–67] and this indirect Eu-Eu interaction may affect the Eu$^{2+}$ g factor. Electron-spin resonance measurements may thus be useful to confirm or refute the hypothesis that the Eu$^{2+}$ Curie constant changes with temperature as suggested in Fig. 5.

**B. High-field magnetization**

The $T$- and $H$-dependent magnetic susceptibility $\chi(T, H)$ was measured for one of the two crystals from each of the Sn-flux and CoAs-flux crystal growths. Figures 6 and 7 show $\chi(T)$ of Sn-flux-grown crystal #2 EuCo$_{1.99(2)}$As$_2$ and CoAs-flux-grown crystal #3 EuCo$_{1.92(4)}$As$_2$, respectively, for various values of $H$ applied in the $ab$ plane ($\chi_{ab}, H \parallel ab$) and along the $c$ axis ($\chi_{c}, H \parallel c$). As shown in Figs. 6(a) and 7(a), the lowest-$T$ data reveal a metamagnetic (MM) transition for $H \parallel ab$ between $H = 3$ and 5 T. In addition, breaks in slope of $\chi(T)$ at each field are observed, signifying the $H$-dependent $T_N$ which decreases with increasing $H$ as expected for an AFM. Figures 6(b) and 7(b) show that $T_N$ is much less sensitive to $H \parallel c$ than to $H \parallel ab$ seen in Figs. 6(a) and 7(a).
FIG. 7. Same as Fig. 6 except that the crystal measured is CoAs-flux-grown crystal #3 EuCo1.92(4)As2.

Figures 8 and 9 show $M(H)$ isotherms at $T = 2$ K with $H$ applied in the $ab$ plane ($M_{ab}, H \parallel ab$) and along the $c$ axis ($M_c, H \parallel c$) obtained for the Sn-flux-grown crystals #1 EuCo1.90(1)As2 and #2 EuCo1.99(2)As2 (Fig. 8), and for the CoAs-flux-grown crystals #3 EuCo1.92(4)As2 and #4 EuCo1.90(2)As2 (Fig. 9). The $M_c(H)$ data are nearly linear in field as predicted at $T \ll T_N$ by MFT for a helix with the applied field along the helix axis, reaching saturation at the perpendicular critical field $H_{c \perp} \sim 10–15$ T, depending on the sample.

The $M_{ab}(H)$ isotherms at $T = 2$ K in Figs. 8 and 9 show what appears to be a field-induced spin-flop (SF) transition at a field $H_{SF}$, with a small hysteresis [see inset of Fig. 8(a)]. The magnetic moment attains its saturation moment $\mu_{sat}$ at the critical field $H_c$ which separates the AFM from the paramagnetic (PM) phases. An additional transition of unknown origin at a field $H_{MM}$ is also seen, with $H_{SF} < H_{MM} < H_c$.

The detailed $M(H)$ isotherms at many temperatures from 2 to 300 K of Sn-flux-grown crystals #1 EuCo1.90(1)As2 and #2 EuCo1.99(2)As2 are shown in Figs. 10 and 11, respectively, and those of CoAs-flux-grown crystals #3 EuCo1.92(4)As2 and #4 EuCo1.90(2)As2 are shown in Figs. 12 and 13, respectively, where parts (a) and (b) of each of the four figures are for $H \parallel ab$ ($M_{ab}$) and $H \parallel c$ ($M_c$), respectively. For the Sn-grown crystals, $M_c(H)$ data in Figs. 10(b) and 11(b) show a negative curvature between 40 and 60 K, but a proportional behavior of $M_c(H)$ is eventually observed at higher temperature ($T > 80$ K). On the other hand, $M_{ab}(H)$ in Figs. 10(a) and 11(a) show clear spin-flop and metamagnetic transitions at $H_{SF}$ and $H_{MM}$, respectively, for $T \approx 40$ K. These SF and MM transitions shift to lower field with increasing temperature. As shown in Figs. 12 and 13, the CoAs-flux-grown crystals exhibit similar behaviors.

The transition fields $H_{SF}$, $H_{MM}$, and $H_c$ versus temperature are taken to be the fields at which $dM/dH$ versus $H$ exhibits a peak or a discontinuity (shown in Fig. 14 for Sn-flux-grown crystals and Fig. 15 for CoAs-flux-grown crystals). The results are listed in Table IV. One sees that $H_{ab}$ is different from $H_{c \perp}$ and the saturation moments of these crystals are larger than...
of the anisotropy on the Néel temperature that would occur in the absence of anisotropy. The definitions and predictions for this type of anisotropy in the presence of Heisenberg exchange interactions are given in Ref. [60] for systems comprised of identical crystallographically-equivalent spins as applies to the Eu sub-lattice in EuCo$_{2-y}$As$_2$. The XY anisotropy field $H_{A_i}$ seen by a given moment $\vec{\mu}_i$ making an angle $\phi_i$ with the positive $x$ axis ($a$ axis here, where the $z$ axis is the $c$ axis) is given by an amplitude $H_{A_0}$ times the projection of the moment onto the $xy$ plane, i.e.,

$$H_{A_i} = H_{A_0} \sin \theta_i (\cos \phi_i \hat{i} - \sin \phi_i \hat{j}). \quad (9)$$

The amplitude is expressed in terms of a more fundamental anisotropy field $H_{A1}$ as

$$H_{A0}(T) = \frac{3H_{A1}}{S+1}\tilde{\mu}_i(T). \quad (10)$$

C. Influence of anisotropy on the magnetic properties

From the above magnetic susceptibility and magnetization data, it is clear that magnetic anisotropy has an important influence on the results. For example, without anisotropy the spin-flop phase for fields in the $ab$ plane would be the stable phase for all fields less than $H_c$. Here the anisotropy must give rise to an easy $ab$ plane ($XY$ anisotropy) because the helix axis is the $c$ axis and the moments are ferromagnetically aligned within a given $ab$ plane.

Here we estimate the strength of the anisotropy in terms of a generic classical anisotropy field. The formulas used here are derived in Ref. [60]. From the value of the anisotropy field parameter $h_{A1}$ to be defined below, we estimate the influence

the theoretical Eu$^{+2}$ value $\mu_{sat} = gS \mu_B/Eu = 7 \mu_B/Eu$, where $g = 2$ and $S = \frac{7}{2}$. As seen later in Sec. VIII, this enhancement is due to $d$-electron spin polarization by the ordered Eu spins.
FIG. 11. Isothermal magnetization $M$ of Sn-flux-grown crystal #2 EuCo$_{1.99(2)}$As$_2$ as a function of magnetic field $H$ at the indicated temperatures for $H$ applied (a) in the ab plane ($M_{ab}, H \parallel ab$) and (b) along the c axis ($M_c, H \parallel c$).

where the reduced ordered and/or field-induced moment $\bar{\mu}_i$ is

$$\bar{\mu}_i(T) = \frac{\mu_i(T)}{\mu_{sat}} = \frac{\mu_i(T)}{g\mu_B S},$$  \hspace{1cm} (11)

where $\mu_i(T)$ is the $T$-dependent magnitude of $\mu_i$. Finally, $H_{A1}$ is expressed in reduced form $h_{A1}$ as

$$h_{A1} = \frac{g\mu_B H_{A1}}{k_B T_{NJ}},$$  \hspace{1cm} (12)

where $T_{NJ}$ is the value that the Néel temperature would have been due to Heisenberg exchange interactions alone (in the absence of anisotropy). Another parameter of the theory is

$$f_J = \frac{\theta_{pJ}}{T_{NJ}},$$  \hspace{1cm} (13)

where $\theta_{pJ}$ is the Weiss temperature in the Curie-Weiss law due to exchange interactions alone.

FIG. 12. (a) Isothermal magnetization $M$ of CoAs-flux-grown crystal #3 EuCo$_{1.92(4)}$As$_2$ as a function of magnetic field $H$ applied (a) in the ab plane ($H \parallel ab$) and (b) along the c axis ($H \parallel c$) at the indicated temperatures.

The Néel temperature $T_N$ in $H = 0$ in the presence of both exchange and anisotropy fields is increased in the presence of the XY anisotropy field, as expected, according to the linear relation

$$T_N = T_{NJ}(1 + h_{A1}).$$  \hspace{1cm} (14)

The anisotropic Weiss temperatures in the Curie-Weiss law for the paramagnetic susceptibility with XY anisotropy are

$$\theta_{pX} = \theta_{pJ},$$  \hspace{1cm} (15a)

$$\theta_{pXY} = \theta_{pJ} + T_{NJ} h_{A1},$$  \hspace{1cm} (15b)

$$\theta_{pXY} - \theta_{pX} = T_{NJ} h_{A1} = \frac{T_N h_{A1}}{1 + h_{A1}},$$  \hspace{1cm} (15c)

$$\frac{\theta_{pXY} - \theta_{pX}}{T_N} = \frac{h_{A1}}{1 + h_{A1}}.$$  \hspace{1cm} (15d)
one to easily determine the parameter
we assume that the Curie constant
where we used Eq. (14) to obtain the third equality. This allows
Thus, the XY anisotropy increases the Néel temperature and
which is equivalent to the approximation $T_N \approx T_{N,J}$. Using the $T_N$ and $\theta_{pab} = \theta_{pc}$ values in Table III, one obtains
$h_{A1} \approx 0.05$ for EuCo$_{2-y}$As$_2$.

$$
\theta_{pab} (\alpha = ab \text{ or } c) \text{ in the PM state at } T > T_N \text{ are independent of } T \text{ with the values given in Table III. We first remove the contributions of the } T\text{-independent susceptibility } \chi_0 \text{ and of anisotropy in the PM state to obtain the } \chi_{0\alpha}(T > T_N) \text{ that would have arisen from exchange interactions alone.}
$$

The $T$-independent susceptibility $\chi_0$ is taken into account at all temperatures according to

$$
\chi_{0\alpha}(T) = \chi_\alpha(T) - \chi_{0\alpha},
$$

where $\chi_\alpha(T)$ is the measured susceptibility and the $\chi_{0\alpha}$ values are given in Table III. We assume that the anisotropy in the PM state arises from sources such as magnetic dipole interactions.

$\theta_{pab} (\alpha = ab \text{ or } c) \text{ in the PM state at } T > T_N \text{ are independent of } T \text{ with the values given in Table III. We first remove the contributions of the } T\text{-independent susceptibility } \chi_0 \text{ and of anisotropy in the PM state to obtain the } \chi_{0\alpha}(T > T_N) \text{ that would have arisen from exchange interactions alone.}

The $T$-independent susceptibility $\chi_0$ is taken into account at all temperatures according to

$$
\chi_{0\alpha}(T) = \chi_\alpha(T) - \chi_{0\alpha},
$$

where $\chi_\alpha(T)$ is the measured susceptibility and the $\chi_{0\alpha}$ values are given in Table III. We assume that the anisotropy in the PM state arises from sources such as magnetic dipole interactions.

where $\chi_\alpha(T)$ is the measured susceptibility and the $\chi_{0\alpha}$ values are given in Table III. We assume that the anisotropy in the PM state arises from sources such as magnetic dipole interactions.

D. Fit of $\chi_{0\alpha}(T < T_N)$ by molecular field theory

In order to fit the low-field $ab$-plane susceptibility $\chi_{0\alpha}(T < T_N)$ by the unified MFT for Heisenberg AFMs in Refs. [56,57], we assume that the Curie constant $C_a$ and Weiss temperature

$$
\theta_{pab}\frac{\theta_{pc}}{T_N} \approx h_{A1} \quad (h_{A1} \ll 1),
$$

which is equivalent to the approximation $T_N \approx T_{N,J}$. Using the $T_N$ and $\theta_{pab} = \theta_{pc}$ values in Table III, one obtains

$$
h_{A1} \approx 0.05 \quad \text{for EuCo$_{2-y}$As$_2$.}
$$

FIG. 13. (a) Isothermal magnetization $M$ of CoAs-flux-grown crystal #4 EuCo$_{1.90(2)}$As$_2$ as a function of magnetic field $H$ applied (a) in the $ab$ plane ($H \parallel ab$) and (b) along the $c$ axis ($H \parallel c$) at the indicated temperatures.

where we used Eq. (14) to obtain the third equality. This allows one to easily determine the parameter $h_{A1}$. Usually the ratio on the left side of Eq. (15d) is small, so one can instead use

$$
\theta_{pab}\frac{\theta_{pc}}{T_N} \approx h_{A1} \quad (h_{A1} \ll 1),
$$

which is equivalent to the approximation $T_N \approx T_{N,J}$. Using the $T_N$ and $\theta_{pab} = \theta_{pc}$ values in Table III, one obtains

$$
h_{A1} \approx 0.05 \quad \text{for EuCo$_{2-y}$As$_2$.}
$$

Thus, the XY anisotropy increases the Néel temperature and also $\theta_{pab}$ by about 5%, or about 2 K for EuCo$_{2-y}$As$_2$.

FIG. 14. Derivative $dM/dH$ versus $H$ for Sn-flux-grown crystals #1 EuCo$_{1.90(1)}$As$_2$ [(a) $H \parallel ab$, (b) $H \parallel c$] and #2 EuCo$_{1.90(2)}$As$_2$ [(c) $H \parallel ab$, (d) $H \parallel c$] for several temperatures $T$ as indicated.

FIG. 15. Derivative $dM/dH$ versus $H$ for CoAs-flux-grown crystals #3 EuCo$_{1.92(1)}$As$_2$ [(a) $H \parallel ab$, (b) $H \parallel c$] and #4 EuCo$_{1.90(2)}$As$_2$ [(c) $H \parallel ab$, (d) $H \parallel c$] for several temperatures as indicated.
and/or single-ion quantum uniaxial $DS^2$ anistropy, for which the magnetic susceptibility tensor is traceless in the PM state [58,59]. Then one obtains the Heisenberg susceptibility $\chi_J$ in the PM state given by

$$\chi_J(T \geq T_N) = \frac{1}{2}[\chi_{Jab}(T) + \chi_{Jc}(T)],$$

(19)
as shown in Fig. 16 for one each of the Sn-flux-grown and CoAs-flux grown crystals. As found above in Sec. IV C, the anisotropy increases $H_{Ts}$ by about 5% and this small change will henceforth be ignored.

Within MFT, for $T \lesssim T_N$ the perpendicular susceptibility $\chi_{Jc}$ is predicted to be independent of $T$, in good agreement with the data in Fig. 16. The normalized $\chi_{Jab}(T \lesssim T_N)/\chi_J(T_N)$ for a helical Heisenberg AFM is given by [56,57]

$$\frac{\chi_{Jab}(T \lesssim T_N)}{\chi_J(T_N)} = \frac{(1 + t^* + 2f_j + 4B^*)(1 - f_j)/2}{(t^* + B^*)(1 + B^*) - (f_j + B^*)^2},$$

(20a)

where

$$B^* = 2(1 - f_j)\cos(kd)[1 + \cos(kd)] - f_j,$$

(20b)

$$t = \frac{T}{T_N}, \quad t^*(t) = \frac{(S + 1)t}{3B'_N(y_0)}, \quad y_0 = \frac{3\tilde{\mu}_0}{(S + 1)t},$$

(20c)
k$d$ is the turn angle between the magnetic moments in adjacent FM-aligned moment layers along the helix (c) axis, the ordered moment versus $T$ in $H = 0$ is denoted by $\mu_0$, the reduced ordered moment $\tilde{\mu}_0 = \mu_0/\mu_{sat}$ is determined by numerically solving the self-consistency equation

$$\tilde{\mu}_0 = B_S(y_0),$$

(21)

$B'_N(y_0) = [dB_S(y)/dy]|_{y=y_0}$, and our definition of the Brillouin function $B_S(y)$ is given in Refs. [56,57].

We fitted the in-plane $\chi_{Jab}(T)$ data in Fig. 16 by Eqs. (20) using $S = \frac{1}{2}$ and the indicated $f_j$ values. For $kd(T)$ we used the neutron-diffraction value $kd(T = 47 \text{ K}) = 0.79\pi$ [44]. In order to fit the lowest-$T$ data, we used $kd(T = 0) = 0.82\pi$ for the Sn-flux-grown crystal and $0.798\pi$ for the CoAs-flux-grown crystal, calculated from Eqs. (20), which are comparable to the experimentally observed value from neutron-diffraction studies [44]. A rough estimated value of $f_j$ is $f_j \sim (20 \text{ K})/(42 \text{ K}) \sim 0.5$. We treated $f_j$ as an adjustable parameter. The $\chi_{Jab}(T \lesssim T_N)$ fits thus obtained are plotted as the solid blue curves in Figs. 16(a) and 16(b) (fits 2). Also shown are the $\chi_{Jab}(T \lesssim T_N)$ curves using the approximate measured values of $f_j$ in Table III (fits 1). The discrepancy between the two fitted curves in each figure is a measure of the deficiency of MFT in predicting $\chi_{Jab}(T)$, as previously discussed in Ref. [57].

V. HEAT CAPACITY

A. Zero-field heat capacity

The heat capacities $C_p(T)$ for Sn-flux-grown crystal #2 EuCo$_{1.99(2)}$As$_2$, CoAs-flux-grown crystal #3 EuCo$_{1.92(4)}$As$_2$, and the nonmagnetic reference compound BaCo$_2$As$_2$ [43] measured in the temperature range from 1.8 to 300 K are shown

### Table IV. Spin-flop transition field $H_{SF}$, metamagnetic transition field $H_{MFM}$, critical field $H_c$, and saturation moment $\mu_{sat}$ at $T = 2 \text{ K}$ of EuCo$_{2-x}$As$_2$ single crystals determined from isothermal $M(H)$ data for fields $H \parallel ab$ and $H \parallel c$.

in Fig. 17. The data exhibit a prominent peak at $T_N = 45.1(2)$ K and $T_S = 40.02(4)$ K for crystals #2 and #3, respectively. Low-temperature $C_p(T)$ vs $T^2$ plots in the range 1.8 to 5 K for the above two crystals and for Sn-flux-grown crystal #6 EuCo$_{1.94(2)}$As$_2$ are shown in the insets of Fig. 17. The data for all three crystals exhibit negative curvature below $\sim 3$ K and hence cannot be fitted by the conventional expression [61]

$$
\frac{C_p(T)}{T} = \gamma + \beta T^2,
$$

where $\gamma$ is the Sommerfeld coefficient associated with the conduction electrons and $\beta$ is the coefficient of the $T^3$ lattice and three-dimensional AFM spin-wave contributions. Below, we attempt to find $\gamma$ by fitting the high-$T$ data. In Table V are shown data obtained for similar isomorphous compounds.

Shown in Fig. 17(c) are plots of $C_p(T)/T$ versus $T$ for the three crystals #2, #3, and #6. One sees that each crystal shows approximately linear behavior over the $T$ range from 2 to 6 K, i.e., that $C_p$ has an approximately $T^2$ contribution over this $T$ range. From preliminary linear spin-wave calculations, this behavior may arise from the temperature-dependent heat capacity of AFM spin waves.

The $C_p(T)$ data for our crystals in the temperature range 120 K $\leq T \leq 280$ K are analyzed using an electronic $\gamma T$ term plus the Debye model for the lattice heat capacity [61]

$$
C_p(T) = \frac{\gamma T}{\Theta_D} + nC_{\text{Debye}}(T/\Theta_D),
$$

$$
C_{\text{Debye}}(T/\Theta_D) = 9R \left(\frac{T}{\Theta_D}\right)^3 \int_0^{\Theta_D/T} \frac{x^4 e^x}{(e^x - 1)^2} dx.
$$

The representation of the Debye function $C_{\text{Debye}}(T/\Theta_D)$ used here is an accurate analytic Padé approximation function of $T/\Theta_D$ [68]. The fits to the $C_p(T)$ data over the temperature range 100 to 280 K by Eq. (23) are shown as the black solid curves in Figs. 17(a) and 17(b) and the fitted values of $\gamma$ and $\Theta_D$ are listed in Table V.

FIG. 17. Temperature dependence of the heat capacity $C_p(T)$ in $H = 0$ for (a) Sn-flux-grown #2 EuCo$_{1.99(2)}$As$_2$, and (b) CoAs-flux-grown #3 EuCo$_{1.92(4)}$As$_2$ crystals. Both panels also show $C_p(T)$ of the nonmagnetic reference compound BaCo$_2$As$_2$ [43]. The black curves are Debye lattice heat capacity model fits to the data between 100 and 280–300 K by Eq. (23). Insets: $C_p(T)/T$ versus $T^2$ for the three crystals #2, #3, and Sn-flux-grown #6 EuCo$_{1.94(2)}$As$_2$. The data do not follow the behavior expected from Eq. (22). (c) Plots of $C_p(T)/T$ versus $T$.
The density of conduction carrier states at the Fermi energy $E_F$, $D_\gamma(E_F)$, is obtained from $\gamma$ according to [61]

$$D_\gamma(E_F) = \frac{3\gamma}{\pi^2 k_B^2}, \quad (24a)$$

which gives

$$D_\gamma(E_F) = \frac{3\gamma}{2.359}\left(\frac{\text{states}}{\text{eV f.u.}}\right) = \frac{1}{2.359}\left[\frac{\text{mJ}}{\text{mol K}^2}\right]. \quad (24b)$$

The $D_\gamma(E_F)$ values calculated for EuCo$_{2-x}$As$_2$ crystals #2 and #3 from their $\gamma$ values using Eq. (24b) are listed in Table V, where values from the literature for similar compounds [29,31,32,43] are listed for comparison with those for our crystals.

The Debye temperature is estimated from the value of $\beta$ in Eq. (22) from the expression [61]

$$\Theta_D = \left(\frac{12\pi^4 n R}{5\beta}\right)^{1/3}, \quad (25)$$

where $n$ is the number of atoms per formula unit ($n = 5 - \gamma$ for EuCo$_{2-\gamma}$As$_2$) and $R$ is the molar gas constant. The values of $\Theta_D$ obtained from the $\beta$ values for other compounds [29,31,32,43] are listed for comparison with those for our crystals in Table V.

The magnetic contribution $C_{\text{mag}}(T)$ to $C_p(T)$ for the EuCo$_{2-x}$As$_2$ crystals is obtained by subtracting $C_p(T)$ of the nonmagnetic reference compound BaCo$_2$As$_2$ from those of the EuCo$_{2-x}$As$_2$ crystals, as shown in Figs. 18(a) and 18(b), respectively. Within the Weiss MFT the discontinuity in the magnetic heat capacity at $T_N$ for a spin $S = \frac{7}{2}$ system is given by

$$\Delta C_{\text{mag}} = \frac{5RS(S+1)}{1+2S+2S^2} = 20.14 \text{ J/mol K}. \quad (26)$$

The jump in the heat capacity at $T_N$ is $\approx 23.2 \text{ J/mol K}$ and $21.74 \text{ J/mol K}$ in the Sn-flux-grown crystal #2 EuCo$_{1.99(2)}$As$_2$ and the CoAs-flux-grown crystal #3 EuCo$_{1.92(4)}$As$_2$, respectively, which are somewhat larger than the prediction (26) of MFT. The discrepancy arises from the difference between the observed $\lambda$ shape and the predicted step shape of $C_{\text{mag}}(T)$ at $T_N$. The nonzero contribution to $C_{\text{mag}}(T)$ for $T_N < T < 100 \text{ K}$ reflects the presence of dynamic short-range AFM ordering of the Eu spins above $T_N$. The hump in $C_{\text{mag}}(T)$ below $T_N$ at $T \sim 15 \text{ K}$ arises naturally within MFT for large $S$ [56]. The solid blue curves in Figs. 18(a) and 18(b) represent the MFT prediction for $C_{\text{mag}}(T)$ calculated for each respective $T_N$ and for $S = \frac{7}{2}$ which are in reasonable agreement with the data for each crystal below the respective $T_N$.

The magnetic entropy $S_{\text{mag}}(T)$ in $H = 0$ is calculated from the $C_{\text{mag}}(T)$ data for each crystal according to $S_{\text{mag}}(T) = \int_0^T \frac{C_{\text{mag}}(T)}{T}dT$ and the results are shown in Fig. 18(c) for Sn-flux-grown crystal #2 EuCo$_{1.99(2)}$As$_2$ and in Fig. 18(d) for CoAs-flux-grown crystal #3 EuCo$_{1.92(4)}$As$_2$. The horizontal

![FIG. 18. Magnetic contributions $C_{\text{mag}}(T)$ and $S_{\text{mag}}(T)$ to the heat capacity and entropy, respectively, of (a), (c) Sn-flux-grown crystal #2 EuCo$_{1.99(2)}$As$_2$ and (b), (d) CoAs-flux-grown crystal #3 EuCo$_{1.92(4)}$As$_2$. In (c), (d), the horizontal dashed line is the theoretical high-$T$ limit $S_{\text{mag}}(T) = R \ln(2S + 1) = 17.29 \text{ J/mol K}$ for Eu$_{\frac{7}{2}}$ with $S = \frac{7}{2}$.](144403-15)
FIG. 19. (a) Heat capacity $C_p$ versus temperature $T$ of Sn-flux-grown crystal #2 EuCo$_{1.99(2)}$As$_2$ in various fields $H \parallel c$ as listed. (b) Magnetic $H_{\perp}-T$ phase diagram constructed from the $C_p(H,T)$ data in (a). The solid blue curve is a fit of the data points by Eq. (27a).

FIG. 20. Same as Fig. 19 except for CoAs-flux-grown crystal #3 EuCo$_{1.92(4)}$As$_2$ instead.

The $H-T$ phase diagrams with $H \parallel c$ in Figs. 19(b) and 20(b) were constructed from the $H_{\perp}$ dependence of $T_N$ obtained from the respective Figs. 19(a) and 20(a).

The MFT prediction for the critical field $H_{\perp}(T)$ at which the AFM state undergoes a second-order transition to the PM state with increasing field at fixed $T$ is given by [56]

$$H_{\perp}(T) = H_{\perp}(0)\bar{\mu}_0(T),$$  \hspace{1cm} (27a)

where the reduced $T$-dependent ordered moment $\bar{\mu}_0(T)$ is obtained by solving Eq. (21) and the zero-temperature critical field is given by

$$H_{\perp}(0) = \frac{3k_B T_N(1-f_J)}{g\mu_B(S+1)}.$$  \hspace{1cm} (27b)

In convenient units where $H_{\perp}(0)$ is expressed in Teslas (1 T $\equiv 10^4$ Oe) and taking $g = 2$ and $S = \frac{7}{2}$ for Eu$^{2+}$, one has

$$H_{\perp}(0) [T] = 0.4962(1-f_J)T_N [K].$$  \hspace{1cm} (27c)

B. High-field heat capacity

Figures 19(a) and 20(a) show $C_p(H,T)$ for Sn-flux-grown crystal #2 EuCo$_{1.99(2)}$As$_2$ and CoAs-flux-grown crystal #3 EuCo$_{1.92(4)}$As$_2$, respectively, measured in various applied magnetic fields up to 9 T with $H \parallel c$. Thus the field direction is perpendicular to the $ab$ plane of the ordered moments in $H = 0$ which we therefore denote as $H_{\perp} \equiv H \parallel c$ [56]. It is evident that the AFM transition temperature $T_N(H_{\perp})$ shifts to lower temperature and that the heat capacity jump at $T_N(H_{\perp})$ decreases with increasing field, both as predicted from MFT in Ref. [56] for a field parallel to the helix axis. The data in

The dashed line in each figure is the theoretical high-$T$ limit $S_{\text{mag}} = R \ln(2S + 1) = 17.29$ J/mol K for $S = \frac{7}{2}$. For each crystal, the entropy reaches $\approx 90\%$ of $R \ln(8)$ at $T_N$ and recovers the full value by $\sim 70$ K.

The $H_{\perp}-T$ phase diagrams with $H \parallel c$ in Figs. 19(b) and 20(b) were constructed from the $H_{\perp}$ dependence of $T_N$ obtained from the respective Figs. 19(a) and 20(a).

The MFT prediction for the critical field $H_{\perp}(T)$ at which the AFM state undergoes a second-order transition to the PM state with increasing field at fixed $T$ is given by [56]

$$H_{\perp}(T) = H_{\perp}(0)\bar{\mu}_0(T),$$  \hspace{1cm} (27a)

where the reduced $T$-dependent ordered moment $\bar{\mu}_0(T)$ is obtained by solving Eq. (21) and the zero-temperature critical field is given by

$$H_{\perp}(0) = \frac{3k_B T_N(1-f_J)}{g\mu_B(S+1)}.$$  \hspace{1cm} (27b)

In convenient units where $H_{\perp}(0)$ is expressed in Teslas (1 T $\equiv 10^4$ Oe) and taking $g = 2$ and $S = \frac{7}{2}$ for Eu$^{2+}$, one has

$$H_{\perp}(0) [T] = 0.4962(1-f_J)T_N [K].$$  \hspace{1cm} (27c)
The values of $T_N$ and $f_2$ for the four crystals studied in this paper are given in Table III. For Sn-flux-grown crystal #2 EuCo$_{1.99(2)}$As$_2$, Eq. (27c) gives

$$H_{c1}(0) = 12.1 \, \text{T},$$

and for CoAs-flux-grown crystal #3 EuCo$_{1.92(4)}$As$_2$, one obtains

$$H_{c1}(0) = 8.9 \, \text{T}.$$  

These values have the same relationship to each other as do the critical fields $H_c$ obtained from $M(H,T=2 \, \text{K})$ data that are listed in Table IV for $H \parallel c$.

Using $H_{c1}(0)$ as a fitting parameter, we fitted the $H_{c1}(T)$ data in Figs. 19(b) and 20(b) by Eq. (27a) and obtained $H_{c1}(0) = 14.8(4) \, \text{T}$ for crystal #2 and $H_{c1}(0) = 12.1(3) \, \text{T}$ for crystal #3. The fits are shown by the solid blue curves in Figs. 19(b) and 20(b), respectively.

**VI. PHASE DIAGRAMS IN THE FIELD-TEMPERATURE PLANE**

From the transitions observed in Figs. 6–15, 19, and 20, the phase diagrams in the $H-T$ plane were constructed and are shown for Sn-flux-grown crystal #2 and CoAs-flux-grown crystal #3 in Figs. 21(a)–21(d), each for both $H \parallel c$ and $H \parallel ab$. For $H \parallel c$, the observed phases are the AFM and PM phases, whereas for $H \parallel ab$, there are AFM, MM, and PM phases. For $H \parallel c$ in Figs. 21(b) and 21(d), the only phase transition line is a second-order transition at the critical field $H_c$ that separates the canted AFM phase from the PM phase. For $H \parallel ab$ in Figs. 21(a) and 21(c), there are three phase transition curves: (1) the first-order spin-flop transition at $H_{SF}$ that separates the canted AFM and SF states; (2) a second-order intermediate metamagnetic transition at $H_{MM}$ of unknown origin that separates SF and MM phases; and (3) the second-order critical field transition curve $H_c$ that separates the MM and PM phases.

**VII. ELECTRICAL RESISTIVITY**

**A. Zero-field resistivity**

The $ab$-plane electrical resistivity $\rho$ as a function of temperature $T$ from 1.8 to 320 K measured in $H = 0$ for Sn-flux-grown crystal #2 and CoAs-flux-grown crystal #3 are shown in Figs. 22(a) and 22(b), respectively. The $\rho(T)$ data for both crystals exhibit metallic behavior. For the Sn-flux-grown crystal #2, the residual resistivity is $\rho_0 = 12.0 \, \mu\Omega \, \text{cm}$ at $T = 1.8 \, \text{K}$ and the residual resistivity ratio is $\text{RRR} \equiv \rho(320 \, \text{K})/\rho(1.8 \, \text{K}) = 3.85$. As shown in the inset of Fig. 22(a), a slope change in $\rho(T)$ occurs at $T_N = 45.0(4) \, \text{K}$, a value consistent with the $T_N$ found from the above $C_p(T)$ and $\chi(T)$ measurements on this crystal.

The $\rho(T)$ for the CoAs-flux-grown crystal #3 is shown in Fig. 22(b), where $\rho_0 = 16.0 \, \mu\Omega \, \text{cm}$ at $T = 1.8 \, \text{K}$ and $\text{RRR} = 2.16$. The AFM transition is observed at $T_N = 40.0(9) \, \text{K}$, as clearly shown in the plot of $d\rho(T)/dT$ in Fig. 22(b) inset (1), again in agreement with $T_N$ found from our $\chi(T)$ and $C_p(T)$ data for this crystal.

The low-$T$ data below $T_N$ were fitted well by the quadratic expression $\rho(T) = \rho_0 + AT^2$ corresponding to electron-electron scattering, as shown by the solid curve in Fig. 22(a) inset (2) for the Sn-flux-grown crystal and in Fig. 22(b) inset (2) for the CoAs-flux-grown crystal, where the fitting parameters are given in Table VI.

The $\rho(T)$ above 50 K was fitted by the Bloch-Grüneisen (BG) model where the resistivity arises from electron-phonon scattering, given by [68]

$$\rho_{BG}(T) = \rho_0 + F \left(\frac{T}{\Theta_R}\right)^5 \int_0^{\Theta_R/T} x^5 dx \left(1 - e^{-x}\right)^{x^5},$$

where $F$ is a numerical constant that describes the $T$-independent interaction strength of the conduction electrons with the thermally excited acoustic phonons and contains the ionic mass, Fermi velocity, and other parameters, $\lambda = \frac{\hbar v_F}{\sqrt{3}k_B T}$, and $\Theta_R$ is the resistively determined Debye temperature [68]. The representation for $\rho_{BG}(T)$ used here is an accurate analytic Padé approximant function of $T/\Theta_R$ [68]. The fits to the data between 50 and 320 K by Eq. (29) are shown as the yellow curves in the main panels of Figs. 22(a) and 22(b), and the fitted parameters are listed in Table VI.

On close examination, the BG model does not provide an optimum fit to the data in Fig. 22. A phenomenological model that can describe the negative curvature in $\rho(T)$ at high $T$ is
The negative curvature in the resistivity at the higher temperatures that is not fitted by the BG model may be either due to interband scattering or weak additional electron-electron scattering originating from the thermal population of higher-lying energy levels [71,72]. A model that can describe the negative curvature \( \rho(T) \) above the ordering temperature is the Bloch-Grüneisen-Mott model, given by [73]

\[
\rho_{\text{BGM}}(T) = \rho_{\text{BG}}(T) - \alpha T^2, \tag{31}
\]

where \( \rho_{\text{BG}}(T) \) is the Bloch-Grüneisen expression as shown by Eq. (29) and \( \alpha \) is the \( s\)-d interband scattering coefficient (Mott coefficient). The fits of the model to the experimental data are shown by the solid green curves in Figs. 22(a) and 22(b) and the fitted parameters are listed in Table VI. In this model, when the mean-free path is shorter than on the order of a few atomic spacings, the scattering cross section is no longer linear in \( T \) because under the influence of the lattice vibrations the \( s \) electrons may make transitions to the unoccupied or partially-filled \( d \) states. As a result, the resistance decreases with increasing temperature compared to the \( \rho_{\text{BG}}(T) \) behavior and shows negative curvature \( (d^2\rho/dT^2 < 0) \).

### B. High-field magnetoresistivity

The \( \rho(T) \) data at selected magnetic fields applied along the \( c \) axis for the EuCo\(_{2+y}\)As\(_2\) crystals grown from Sn flux (#2) and CoAs flux (#3) are shown in Figs. 23(a) and 24(a), respectively. For the Sn-flux-grown crystal, the \( \rho(T)/dT \) data in Fig. 23(a) show that the peak position at \( T_N \) shifts from 45.0(4) K at \( H = 0 \) to 35.2(5) K at \( H = 8 \) T and the transition broadens and smears out progressively with increasing field up to 8 T. For the CoAs-grown crystal, the shift of \( T_N \) with increasing field

\( ^a \)Grown in Sn flux with H\(_2\)-treated Co powder.

\( ^b \)Grown in CoAs flux with H\(_2\)-treated Co powder.
FIG. 23. (a) In-plane electrical resistivity \( \rho \) of Sn-flux-grown crystal #2 EuCo\(_{1.99(2)}\)As\(_2\) as a function of temperature \( T \) measured in the indicated magnetic fields \( H \parallel c \). For clarity, the data for successive fields are offset from each other by 2 \( \mu \Omega \text{ cm} \) as indicated. (b) Temperature derivative \( d\rho/dT \) versus \( T \) obtained from the data in (a). (c) Magnetoresistance MR versus applied field at temperatures ranging from 2 to 20 K for current density \( J \parallel ab \) and magnetic fields \( H \parallel c \).

FIG. 24. Same as Fig. 23 but with CoAs-flux-grown single crystal #3 EuCo\(_{1.92(4)}\)As\(_2\) instead. The field-dependent \( \rho(H, T) \) data for CoAs-flux-grown and Sn-flux-grown crystals show different shapes below \( T_N \).
The transverse magnetoresistance (MR), defined as $\text{MR}(H,T) \equiv 100\%(\rho(H,T) - \rho(0,T))/\rho(0,T)$, calculated from the $\rho(H)$ data are shown in Figs. 23(c) and 24(c). At $T = 2$ K, the MR of the Sn-flux-grown crystal is negative and attains a maximum negative value of $-0.79\%$ at 8 T whereas for the CoAs-flux-grown crystal, the MR at 9 T is $-6.6\%$ at 2 K. The negative curvature in MR versus $H$ is enhanced as $T$ increases, leading to a MR of a $-4.4\%$ for the Sn-flux-grown crystal at $H = 8$ T and $T = 45$ K, and a MR of $-7.6\%$ for the CoAs-flux-grown crystal at $H = 9$ T and $T = 25$ K. At higher temperatures $T > T_N$, the MR shows positive curvature at low fields, and becomes positive at $T > 100$ K. Extended discussions of MR in nonmagnetic metals can be found in Ref. [74].

VIII. ELECTRONIC STRUCTURE CALCULATIONS

In order to gain further insight on the enhanced Eu moments, we performed electronic structure calculations. Our goals were (i) to check whether there is an enhanced polarization that could justify the observed enhanced effective moment, (ii) if so, to find where it resides, and (iii) how the density of states relates to the measured specific heat.

We performed total energy and band structure calculations employing the implementation of density functional theory in the code Dmol$^3$ [75] within Materials Studio. This was done for the stoichiometric 122 system. Since we have permanent magnetic moments due to the $5S_7/2$ configuration of the Eu $4f$ electrons, we must do spin-polarized calculations; otherwise DFT would wrongly split the $4f$ electrons equally over spin-up and spin-down states. We performed a calculation with all Eu spins pointing in the same direction, and another with alternating orientation in consecutive $ab$ planes (from here on referred as configurations F and A, respectively). Although these are only two amongst the infinitely many configurations visited by the system in a paramagnetic state, such a comparison can give us information on how the relative orientation of the local spins can affect the polarization of the conduction band. This is motivated by the fact that EuCo$_2$As$_2$ is metallic and it is very likely that exchange interactions between the local moments and the conduction band play a role in the magnetic properties. In addition, the antiferromagnetic ground state should result in zero net polarization of the conduction electrons, while this does not have to be the case for other configurations.

Our calculations included all electrons (i.e., no pseudopotential was used) in the scalar relativistic approximation. We employed the Perdew-Burke-Ernzerhof exchange correlation functional [76] in the generalized gradient approximation. The Kohn-Sham quasiparticle states were sampled over a $\mathbf{k}$-space grid with $7 \times 7 \times 9$ points and the $\mathbf{k}$-space integration for the total energy was done with the tetrahedron method [77]. Self-consistency tolerance was set to $2 \times 10^{-4}$ Rydberg for the total energy per cell.

The band structures in both configurations are shown in Fig. 25. Projected density of states on atomic orbital type for configurations F and A are shown in Figs. 26 and 27, respectively. One can notice in Fig. 26 that the polarization induced by the local Eu moments resides in the $d$ states, which are mainly coming from cobalt atoms. Following the tetrahedral coordination of Co by As, one can roughly divide the $d$ orbitals into two sets, the $e_g$ doublet and the $t_{2g}$ triplet. The former is less affected by the As $p$ states and appears less hybridized between $-2.5$ eV and $-1$ eV. The $t_{2g}$ states mix more strongly with the As $p$ states resulting in a bonding fraction between $-4$ eV and $-3$ eV (with dominant contribution from As $p$ orbitals), and an antibonding component at and above the Fermi
FIG. 26. Electronic density of states (DOS) from DFT calculations for EuCo$_2$As$_2$ with the Eu moments in configuration F. The projection of the $s$ states is shown as the solid red curve, $p$ as the short-dotted blue curve, $d$ as the dashed green curve, and $f$ as dotted-black curve.

energy $E_F$ (with dominant cobalt $d$ contribution). While $d$ states with different spin orientations are shifted with respect to each other at all energies in the F configuration, the $e_g$ states have no net polarization as they appear fully occupied below $E_F$. The net polarization originates from the $t_{2g}$ states around $E_F$. States with the same spin orientation as the Eu moments are stabilized (shifted down in energy) and those with the opposite orientation are shifted up (destabilized), resulting in a net enhanced moment per Eu atom.

In configuration F, the projection of the electronic states onto atomic centers gives 2 spin for europium ions and 0.26 for the states belonging to cobalt. In configuration A, the total projected moment on the Eu sites remains as $\frac{7}{2}$ while the cobalt states display a negligible polarization of $\pm 0.01$. This is in agreement with the conclusion from neutron-diffraction experiments that Co makes no contribution to the moments in the low-temperature ordered AFM phase. It is also consistent with the observation that in the paramagnetic state, the fluctuating moments have an enhanced value. As a very rough estimate, we can consider that having two Co per Eu, which are only polarized half of the time and fully correlated with the orientation of the Eu spins, the effective moment in $\mu_B$ per Eu turns out to be $\mu_{eff} \approx 2\sqrt{(7/2 + 0.26) \times (7/2 + 0.26 + 1)} \approx 8.5$. This estimate is suggestively similar to the values in Table III obtained from the susceptibility fits.

The total electronic density of states at the Fermi level is predicted to have a very similar value of $D(E_F) \approx 5$ states/eV per f.u. for both F and A configurations. This value is comparable to the value of $\approx 6$ states/eV f.u. obtained in Table V from the high-temperature fit of Eqs. (23) to $C_p(T)$. The experimentally derived value of $D(E_F)$ is indeed expected to be larger than the band-structure value due to enhancement of the experimental value by the electron-phonon interaction.

FIG. 27. Electronic density of states (DOS) from DFT calculations for EuCo$_2$As$_2$ with the Eu moments in configuration A. The projection of the $s$ states is shown as the solid red curve, $p$ as the short-dotted blue curve, $d$ as the dashed green curve, and $f$ as dotted-black curve.

FIG. 28. Generic helix AFM structure [57]. Each arrow represents a layer of moments perpendicular to the $z$ axis that are ferromagnetically aligned within the $xy$ plane and with interlayer separation $d$. The wave vector $k$ of the helix is directed along the $z$ axis. The magnetic moment turn angle between adjacent magnetic layers is $kd$. The exchange interactions $J_{z1}$ and $J_{z2}$ within the $J_0$-$J_{z1}$-$J_{z2}$ Heisenberg MFT model are indicated.

IX. HEISENBERG EXCHANGE INTERACTIONS

We now estimate the intralayer and interlayer Heisenberg exchange interactions within the minimal $J_0$-$J_{z1}$-$J_{z2}$ MFT model for a helix in Fig. 28 [78], where $J_0$ is the sum of all Heisenberg exchange interactions of a representative spin to all other spins in the same spin layer perpendicular to the helix.
(c) axis, \( J_{1z} \) is the sum of all interactions of the spin with spins in an adjacent layer along the helix axis, and \( J_{2z} \) is the sum of all interactions of the spin with spins in a second-nearest layer.

Within this model \( kd \), \( T_N \) and \( \theta_p \) are related to these exchange interactions by [56,57]

\[
\cos(kd) = \frac{J_{1z}}{4J_{2z}}, \tag{32a}
\]

\[
T_N = -\frac{S(S + 1)}{3k_B}[J_0 + 2J_{1z} \cos(kd) + 2J_{2z} \cos(2kd)], \tag{32b}
\]

\[
\theta_p = -\frac{S(S + 1)}{3k_B}(J_0 + 2J_{1z} + 2J_{2z}), \tag{32c}
\]

where a positive (negative) \( J \) corresponds to an AFM (FM) interaction. The three exchange constants \( J_0, J_{1z}, \) and \( J_{2z} \) are obtained by solving Eqs. (32) using \( S = \frac{7}{2}, \) \( kd = 0.79\pi, \) and the \( T_N \) and \( \theta_p = \theta_{p,\text{ave}} \) values in Table III, and the results are listed in Table VII.

The classical energy per spin in an ordered spin system in \( H = 0 \) with no anisotropy and containing identical crystallographically equivalent spins is

\[
E_i = \frac{1}{2} \sum_j J_{ij} S(R_i) \cdot S(R_j), \tag{33}
\]

where the factor \( \frac{1}{2} \) arises because the energy of an interacting spin pair is equally shared between the two spins in the pair, the sum is over the neighboring ordered spins \( S(R_i) \) of the given central spin \( S(R) \), and the \( J_{ij} \) are the Heisenberg exchange interactions between each respective spin pair. Here, we only consider Bravais spin lattices where the position of each spin is a position of inversion symmetry of the spin lattice such as the body-centered-tetragonal (bct) spin lattice in Fig. 29. We further restrict our attention to coplanar AFMs in which the ordered moments in the ordered AFM state are aligned in the \( xy \) plane such as for the coplanar helix.

The expression for the classical ground-state energy per spin obtained from Eq. (33) is

\[
E_i = \frac{S^2}{2} \sum_j J_{ij} \cos \phi_{ji}, \tag{34}
\]

where \( \cos \phi_{ji} = \hat{S}(R_i) \cdot \hat{S}(R_j) \) and \( \phi_{ji} \) is the azimuthal angle within the \( xy \) plane between the ordered spins \( S(R_j) \) and \( S(R_i) \). Within the \( J_0-J_{1z}-J_{2z} \) model one obtains

\[
E_i = \frac{S^2}{2}(J_0 + 2J_{1z} \cos(kd) + 2J_{2z} \cos(2kd)), \tag{35}
\]

where we take the ground-state turn angle to be \( kd = 0.79\pi \) for all EuCo\( _{2-x} \)As\( _2 \) samples [44]. Using \( S = \frac{7}{2} \) and the values of \( J_0, J_{1z}, \) and \( J_{2z} \) in Table VII, one obtains the classical ground-state energies per spin \( E_i \) listed in Table VII. The values are in the range \(-46 \) to \(-52 \) K, with magnitudes that are similar to the Néel temperatures themselves as might have been expected.

The bct Eu sublattice of EuCo\( _{2-x} \)As\( _2 \) is shown in Fig. 29, where the measured ratio \( c/a = 2.93 \) is to scale. Assuming that the exchange interactions \( J_A, J_B, \) and \( J_C \) in the figure are the only ones present, in terms of the interactions in the Eu

\[
J_0-J_{1z}-J_{2z} \text{ model one has}
\]

\[
J_0 = 4J_A, \quad J_{1z} = 4J_B, \quad J_{2z} = J_C. \tag{36}
\]

Then, using the values of \( J_0, J_{1z}, \) and \( J_{2z} \) in Table VII one obtains the \( J_A, J_B, \) and \( J_C \) values which are listed in Table VII.

X. SUMMARY

Investigations of the physical properties of EuCo\( _{2-x} \)As\( _2 \) crystals with the ThCr\( _2 \)Si\( _2 \) structure that were grown in Sn and CoAs fluxes are reported. For most of our crystals, we find \( \approx\)5% vacancies on the Co sites, similar to the value of 7% vacancies on the Co sites in CaCo\( _{2-x} \)As\( _2 \) [29,30].

In-plane electrical resistivity \( \rho(T) \) measurements indicate metallic behavior of the two crystals studied, with a kink in \( \rho(T) \) at the respective \( T_N \). High-field \( \rho(T) \) data with \( H \parallel c \) reveal negative magnetoresistance, reaching \( \approx \)5% at \( T = 2 \) K and \( H = 9 \) T.

EuCo\( _{2-x} \)As\( _2 \) contains Eu\(^{\text{+2}} \) ions with expected spin \( S = \frac{7}{2} \) and \( g = 2 \), which exhibit AFM ordering at \( \approx 45 \) K for the Sn-flux-grown crystals and \( \approx 41 \) K for the CoAs-flux-grown crystals. We obtained good fits using molecular-field theory (MFT) to the low-field \( ab \)-plane magnetic susceptibility of the helical AFM structure below \( T_N \) with the Eu moments aligned in the \( ab \) plane. Zero-field heat capacity \( C_p \) measurements were carried out and the magnetic contribution \( C_{\text{mag}}(T) \) was extracted. The \( C_{\text{mag}}(T) \) data below \( T_N \) were fitted reasonably well by MFT. The \( C_{\text{mag}}(T) \) above \( T_N \) is nonzero, indicating the presence of dynamic short-range AFM ordering above \( T_N \). Thus, the molar magnetic entropy \( S_{\text{mag}} \) at \( T_N \) is only about 90% of the completely disordered value \( R \ln 8 \), the remainder being recovered by about 70 K.
The high-field magnetization in the $ab$ plane below $T_N$ exhibits a spin-flop-like transition followed by a second-order metamagnetic transition to an unknown AFM structure and then a second-order AFM to paramagnetic (PM) transition, whereas high-field $c$-axis measurements reveal only the expected second-order canted-AFM to PM transition. High-field $C_p(T)$ measurements with $H \parallel c$ also only reveal the AFM to PM transition, where the $T_N$ and the heat capacity jump at $T_N$ both decrease with increasing $H$. Phase diagrams in the $H \parallel ab$ and $H \parallel c$ versus $T$ planes were constructed from the high-field magnetization and heat capacity results.

A primary goal of this work was to investigate a possible enhancement of the Eu magnetic moment for crystals of EuCo$_{2-y}$As$_2$ prepared under different conditions. Shown in Table VIII is a summary of the effective moments $\mu_{\text{eff}}$ obtained from modified Curie-Weiss law fits in the paramagnetic state at $T > T_N$ for five of the crystals studied here and the corresponding saturation moments $\mu_{\text{sat}}$ obtained from high-field $M(H)$ isotherms at $T = 2$ K of EuCo$_{2-y}$As$_2$ from Tables III and IV, respectively. These two moments are given in general for a spin with no contribution of orbital moments by

$$\mu_{\text{eff}} = g\sqrt{S(S+1)} \mu_B,$$

(37a)

$$\mu_{\text{sat}} = gS \mu_B.$$  

(37b)

For spin-only Eu$^{+2}$, one expects $S = \frac{7}{2}$ and $g \approx 2$, yielding

$$\mu_{\text{eff}0} = 7.94 \mu_B/\text{Eu},$$

(38a)

$$\mu_{\text{sat}0} = 7.00 \mu_B/\text{Eu}.$$  

(38b)

Comparing these values with those in Table VIII shows that both Sn-flux-grown and CoAs-flux-grown crystals show significant enhancements of $\mu_{\text{eff}}$ and/or $\mu_{\text{sat}}$. Also shown in the table are the relative enhancements of the observed moments with respect to the expected moments as expressed by $\Delta \mu/\mu_0 = (\mu_{\text{obs}} - \mu_0)/\mu_0$. One sees that the effective moment $\mu_{\text{eff}}$ values are all enhanced by 6.7% to 9.1% with respect to the unenhanced value. The saturation moments $\mu_{\text{sat}}$ also exhibit enhancements, but the enhancement is more variable, from 0.4% to 8.4%.

Table VII. Exchange constants in the $J_0$-$J_1$-$J_2$ model obtained from Eqs. (32) and the corresponding classical ground-state energies per spin $E_i$ calculated from Eq. (35). The exchange interactions between Eu spins $J_A$, $J_B$, and $J_C$ obtained using Eq. (36) are also listed. Negative $J$ values are FM and positive values are AFM.

\[\Delta \mu_{\text{eff}} = \mu_{\text{eff}} - \chi_T S/3 \] for several other 122-type compounds containing Eu\(^{2+}\) ions. One sees that the respective values for all these compounds are less than the expected value. This divergence between the values of the Eu moments in EuCo\(_{2}\)As\(_2\) and those of the other compounds starkly illustrates the anomalous enhancement of the Eu moments in EuCo\(_{2}\)As\(_2\).

From Eqs. (37), enhancement of the Eu moment could arise from enhancement of \( g \), of \( S \), or both. Such an enhancement occurs in ferromagnetic Gd metal containing Gd\(^{3+}\) ions with \( S = \frac{7}{2} \), where the saturation moment at 4.2 K is 7.55(2) \( \mu_B/\text{Gd} \) [83]. This enhancement above the expected value of 7 \( \mu_B/\text{Gd} \) was found from electronic structure calculations to arise from polarization of the conduction d-band electrons by the Gd spins [84]. The enhancement is similar to the maximum enhancements of the moment of isoelectronic Eu\(^{2+}\) with \( S = \frac{7}{2} \) in Table VIII. It has been inferred from neutron-diffraction studies [46] that the Co atoms do not contribute to the ordered moment of EuCo\(_{2}\)As\(_2\) below \( T_N \). It therefore seems likely that the effective spin value is increased by polarization of the conduction carrier spins by the ordered Eu spins. This expectation is indeed confirmed by our electronic structure calculations.

**ACKNOWLEDGMENTS**

We thank S. Gupta for the \( \text{H}_2 \) treatment of our Co powder starting material, G. Lindemann for his help during the early stages of this work, and M. Shatruk for sending us his published \( \chi(T) \) data for an EuCo\(_{2}\)As\(_2\) crystal [44]. The research at Ames was supported by the U. S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering. Ames Laboratory is operated for the U. S. Department of Energy by Iowa State University under Contract No. DE-AC02-07CH11358.
