Competing pairing interactions responsible for the large upper critical field in a stoichiometric iron-based superconductor CaKFe4As4

Abstract
The upper critical field of multiband superconductors is an important quantity that can reveal details about the nature of the superconducting pairing. Here we experimentally map out the complete upper-critical-field phase diagram of a stoichiometric superconductor, CaKFe4As4, up to 90T for different orientations of the magnetic field and at temperatures down to 4.2K. The upper critical fields are extremely large, reaching values close to ∼3Tc at the lowest temperature, and the anisotropy decreases dramatically with temperature, leading to essentially isotropic superconductivity at 4.2K. We find that the temperature dependence of the upper critical field can be well described by a two-band model in the clean limit with band-coupling parameters favoring intraband over interband interactions. The large Pauli paramagnetic effects together with the presence of the shallow bands is consistent with the stabilization of an FFLO state at low temperatures in this clean superconductor.

I. INTRODUCTION

The upper critical field, $H_c^2$, is an important property of superconductors that defines their limit for practical applications. It also describes the complex interplay between different pairing gaps and symmetry and can shed light on the nature of the superconducting mechanism. Furthermore, the temperature dependence of the upper critical field can also provide evidence for the presence of the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state [1,2], in which the order parameter provides a relatively high value close to the lowest temperature, and the anisotropy decreases dramatically with temperature, leading to essentially isotropic superconductivity at 4.2 K. We find that the temperature dependence of the upper critical field can be well described by a two-band model in the clean limit with band-coupling parameters favoring intraband over interband interactions. The large Pauli paramagnetic effects together with the presence of the shallow bands is consistent with the stabilization of an FFLO state at low temperatures in this clean superconductor.

The upper critical field of multiband superconductors is an important quantity that can reveal details about the nature of the superconducting pairing. Here we experimentally map out the complete upper-critical-field phase diagram of a stoichiometric superconductor, CaKFe$_4$As$_4$, up to 90 T for different orientations of the magnetic field and at temperatures down to 4.2 K. The upper critical fields are extremely large, reaching values close to $\sim 3T_c$ at the lowest temperature, and the anisotropy decreases dramatically with temperature, leading to essentially isotropic superconductivity at 4.2 K. We find that the temperature dependence of the upper critical field can be well described by a two-band model in the clean limit with band-coupling parameters favoring intraband over interband interactions. The large Pauli paramagnetic effects together with the presence of the shallow bands is consistent with the stabilization of an FFLO state at low temperatures in this clean superconductor.

II. EXPERIMENTAL DETAILS

Single crystals of CaKFe$_4$As$_4$ were grown in the Ames Laboratory, as discussed elsewhere [5,17]. Robust electrical
contacts were achieved using indium solder, giving contact resistances of less than 0.5 Ω. Samples were measured using the standard four- and five-point AC lock-in techniques and a current of 1 mA. We investigated several high-quality single crystals, with large residual resistivity ratios \( \sim 14.5 \) [\( \text{RRR} = \rho(300 \text{ K})/\rho(36 \text{ K}) \)], small residual resistivity, \( \rho_0 \sim 9.4 \mu\Omega\text{cm} \), and sharp superconducting transitions, \( \Delta T_c \sim 0.1 \text{ K} \) [see Figs. 1(f) and 5(c)]. Transport measurements were performed in Oxford up to 16 T in a Quantum Design PPMS in constant magnetic fields and for different magnetic field orientations \( H/|c| \) and \( H/|(ab)\). Pulsed magnetic-field measurements were performed at LNCMI Toulouse, using a 70 T single coil and a 90 T dual coil at constant temperatures below 35 K for both field orientations (an example is shown in Fig. 6).

III. UPPER CRITICAL FIELD FROM TRANSPORT MEASUREMENTS

Figure 1(a)–1(b) shows resistivity against temperature for different fixed magnetic fields for orientations of the sample in relation to the applied magnetic field. As the magnetic field increases, the superconducting transition becomes broader and suppressed faster for \( H/|c| \) by 5 K in 16 T [Fig. 1(a)], as compared with the \( H/|(ab)\) case for which \( H_c2 \) only changes by 2 K in 16 T [Fig. 1(b)], as the orbital effects are less effective in suppressing superconductivity in this orientation. These data are used to extract the upper critical field near \( T_c \), defined as the offset field, as shown in Figs. 5(a) and 5(b). Due to the high crystallinity of our samples that display sharp superconducting transitions, we find that the critical temperature from magnetization measurements is similar to the offset temperature determined from transport measurements [Fig. 5(a)]. To completely suppress the superconductivity of CaKFe\(_4\)As\(_4\), we have used pulsed magnetic fields up to 90 T. Resistivity data against magnetic fields up to 90 T measured at fixed temperature are shown in Figs. 1(c) and 1(d) for the two different orientations. Despite the strong disparity in the degree of suppression of superconductivity between the two field directions close to \( T_c \), at the lowest measurable temperature of 4.2 K, the normal state is reached at a similar field \( \sim 85 \text{ T} \) for both orientations.

IV. UPPER-CRITICAL-FIELD PHASE DIAGRAM

Based on these experimental data, we have constructed the complete upper-critical-field phase diagram of CaKFe\(_4\)As\(_4\) down to 4.2 K as shown in Fig. 2(a) for the two orientations. Our results are in good agreement with previous studies up to 60 T for both offset and onset critical fields [7] [see Figs. 9(a) and 9(b)] and reveal extremely large upper critical fields, reaching almost \( \sim 3 T_c \) at the lowest temperatures. These values are above the Pauli paramagnetic limit, \( \sim 1.85 T_c \), estimated to be \( \sim 65 \text{ T} \) for a single-band superconductor and assuming \( g = 2 \) and the weak-coupling limit. The anisotropy of the upper critical field, defined as the ratio of the upper critical field for different orientations, \( \Gamma = H_c^a/H_c^c \), drops dramatically with decreasing temperature from \( \sim 4 \) to 1, as shown in Fig. 2(b). Interestingly, the upper critical fields for the two orientations cross at \( T \sim 4.2 \text{ K} \), leading to isotropic superconducting behavior in the low-temperature limit. This phenomenon has been found in optimally doped
FIG. 2. (a) Upper critical fields as a function of temperature in CaKFe$_4$As$_4$ when $H \parallel c$ (solid squares) and $H \parallel (ab)$ (open triangles), together with previous reported data measured up to 60 T from Ref. [7]. (b) The temperature dependence of coherence length extracted close to $T_c$, as described in the Appendix. The $H_c(0)$ values were used to find the zero-temperature coherence lengths. The horizontal dashed line represents the 3D-2D crossover when coherence length $\sim c/\sqrt{2}$. The anisotropy $\Gamma = H_{c2}/H_c$ on the right axis approaches $\Gamma = 1$ at $\sim 4.2$ K. Solid lines are guides to the eye. (c) Upper critical fields for $H \parallel c$ (black squares) and $H \parallel (ab)$ (black triangles) scaled by the superconducting transition temperature, $T_c$, and the slope near $T_c$ from the WHH model against reduced temperature $T/T_c$. The dashed blue and red lines are fits to the WHH model for $H \parallel c$ and $H \parallel (ab)$ using different values of $\alpha$. Deviation from the WHH model occurs at low temperatures for both field orientations.

iron-based superconductors, such as FeSe$_{0.5}$Te$_{0.5}$ [18,19] and (Ba,K)Fe$_2$As$_2$ [20]. This behavior reflects the large Pauli paramagnetic effects in iron-based superconductors and the influence of Fermi surface details on orbital effects [20]. The Fermi surface of CaKFe$_4$As$_4$ has significant warping for the outer electron and hole band that can potentially allow circulating currents out of plane [see Fig. 4(d) in the Appendix]. Furthermore, the calculated anisotropy of the penetration depth based on plasma frequencies (as in Ref. [21]) is $\Gamma = \lambda_c/\lambda_{ab} \sim 4.5$, (see Fig. 4) similar to the measured anisotropy close to $T_c$ [Fig. 2(b)], suggesting that the Fermi surface details play an important role in understanding its superconducting properties.

Having experimentally determined the upper critical fields for different orientations in magnetic field, we can extract the associated coherence lengths in different temperature regimes, as detailed in the Appendix. In the vicinity of $T_c$, the Ginzburg-Landau coherence lengths shown in Fig. 2(b) are $\xi_{ab}^{GL} = 1.66(4)$ nm and $\xi_c^{GL} = 0.53(2)$ nm for CaKFe$_4$As$_4$, similar to previously reported values [7]. In the low-temperature limit, we find coherence lengths of $\xi_{ab} = 1.83(3)$ nm and $\xi_c = 1.87(6)$ nm, as shown in Fig. 7. This demonstrates the presence of an isotropic superconducting state at lowest temperature in CaKFe$_4$As$_4$. The coherence lengths approach the 3D to 2D crossover close to $c/\sqrt{2}$ $\sim$ 0.911 nm, as shown in Fig. 2(b) [5,22]. The low-temperature extracted $\xi$ values are larger than $\sim$0.7 nm reported from scanning tunnelling microscopy (STM) measurements, which probe locally the vortex lattice rather than an overall averaged effect [23]. Knowing the coherence length allows us to estimate the depairing current density, $J_d$, as described in the Appendix [24]. Previous magnetization data reported a value of $\mu_0H_{c1} = 22(1)$ mT when $H \parallel c$ at low temperatures which, combined with $H_c2$ reported here, give $\kappa \sim 99(2)$ and $\lambda = 183(6)$ nm. Using this value for the penetration depth and $\xi = 1.86(3)$ nm gives $J_d = 1.61(9) \times 10^8$ A/cm$^2$, which is one of the largest among iron-based superconductors. This supports the extremely large critical current densities, reported previously for CaKFe$_4$As$_4$ in Ref. [14]. The small coherence length of CaKFe$_4$As$_4$ is compatible with the presence of the large upper critical field, consistent with small Fermi velocities and high $T_c$ values of CaKFe$_4$As$_4$ ($\xi \sim h\nu_F/(2\pi k_B T_c)$ [1]). Surface superconductivity can survive in a thin layer of thickness $\sim \xi$ in systems with clean surfaces and it can lead to a critical field larger than $H_c2$. To establish the importance of those effects, future angular-dependent studies would be necessary to identify the role played by surface superconductivity in CaKFe$_4$As$_4$ close to $T_c$. Using the extrapolated zero-temperature normal state resistivity $\rho_0 \sim 9.4 \mu\Omega$cm in Fig. 1(f) and carrier concentrations from Ref. [7], we can estimate a mean-free path of $\ell = 26.6$ nm. Since the mean-free path due to elastic scattering from impurities is far larger than the coherence length, $\xi(0) \ll \ell$, CaKFe$_4$As$_4$ can be described as being in the clean limit. Resistivity data in Fig. 1(f) also show a sharp superconducting transition indicating a high-quality single crystal. Furthermore, the extrapolated high-field resistivity at low temperatures [see Fig. 4(d)] displays a $T^2$ dependence indicative of a Fermi-liquid behavior that extends up to $\sim 55$ K.
To assess the role of orbital and Pauli paramagnetic effects on the upper critical field of CaKFe$_4$As$_4$, we first describe the temperature dependence of the upper critical field using the three-dimensional Werthamer-Helfand-Hohenberg (WHH) model [25], with the inclusion of spin paramagnetism effects. The slope close to $T_c$ ($H_{c2} = \frac{-|dH_{c2}/dT|}{T_c-T_c}$) is used to estimate the zero-temperature orbital upper critical field and $H_{c2}^{orb} = 0.73T_c$ for the clean limit (0.69$T_c$ in the dirty limit) for a single-band weak-coupling superconductor with ellipsoidal Fermi surface [26]. We find that the orbital pair breaking dominates the temperature dependence for $H$||c down to 10 K, below which it deviates, as shown in Fig. 2(c). However, when the magnetic field is aligned along the conducting $(ab)$ plane, a Pauli pair-breaking contribution has to be included which reduces the orbital-limited critical field by $\mu_0H_F = \mu_0H_{c2}^{orb}/\sqrt{1+\alpha^2}$, where $\alpha$ is the Maki parameter. The extracted Maki parameter $\alpha$ is small where the orbital effects dominate $\alpha \sim 0.25$ for $H$||c, but it becomes significant reaching $\alpha \sim 4.2$ for $H$||(ab) [see Fig. 2(e)]. This value is close to that of FeSe$_0.06$Te$_{0.6}$ single crystals where $\alpha \sim 5.5$, suggesting that the upper critical field is dominated by Pauli paramagnetic effects [27]. Strong paramagnetic effects are an important signature of optimally doped iron-based superconductors [28–32]. For a clean isotropic single band, the Maki parameter is given by $\alpha = \pi^2\Delta/(4E_F)$. The values of the measured superconducting gap $\Delta$ varies between 2.4 – 10 meV whereas the Fermi energies vary significantly for different bands, being smallest for the inner hole band, $\alpha \sim 3$ meV and the shallow electron band $\delta \sim 10$ meV [4,33]. The band-structure calculation predicts four electron pockets centered at the $M$ point, as shown in Fig. 4. Experimentally, only one electron pocket can be resolved in experiments due to a significant intrinsic linewidth and the fact that the bottom of these bands is located very close to Fermi level [4]. Thus, the presence of the shallow bands, together with the small Fermi energies $E_F$ and large superconducting gap $\Delta$ create conditions for large $\alpha$ and Pauli pair-breaking.

V. UPPER CRITICAL FIELD DESCRIBED BY A TWO-BAND MODEL

To describe the complete temperature dependence of $H_{c2}(T)$ for CaKFe$_4$As$_4$, including the upturn below $\sim 10$ K for both orientations, a two-band model in the clean limit is considered, as detailed in Ref. [1] and in the Appendix. This model accounts for the presence of two different bands with interband scattering ($\lambda_{11}$, $\lambda_{22}$) and intraband effects ($\lambda_{12}$, $\lambda_{21}$) and includes paramagnetic effects and allows for the presence of an FFLO inhomogeneous state at high fields and low temperatures [1]. An FFLO state is characterized by a real-space modulation of the superconducting order parameter either in amplitude or phase such that the system energy is minimized under the constraints of a large Zeeman energy and superconducting condensation energy [2]. As the FFLO wave vector $Q$ appears spontaneously below a certain temperature, $T_{FFLO}$, the spinodal instability line in $H_{c2}(T)$ at a finite $Q$ acquires the characteristic upturn [1].

In most iron-based superconductors, the pairing is to be mediated by spin fluctuations leading to a sign changing $s_\pm$ order parameter. In this case, upper critical fields are generally described by dominant interband coupling parameters with $\lambda_{11} = \lambda_{22} = 0$ and $\lambda_{12} = \lambda_{21} \sim 0.5$. However, in these multiband systems, orbital fluctuations can dominate the pairing interactions in certain conditions favoring a gap with equal sign on each pocket, resulting in the $s^{\pm}$ pairing [36] ($\lambda_{11}\lambda_{22} \gg \lambda_{12}\lambda_{21}$).

To model the upper critical fields for both field orientations, we have considered different input parameters from previous experiments on CaKFe$_4$As$_4$. For example, the ratio between the extreme velocities of the Fermi surfaces is taken from ARPES experiments [33] and gives a starting value of $\eta_c \sim 0.02$, which is the squared velocity ratio between the two bands. Upper critical field simulations have a strong sensitivity to $\eta_c$ values, as shown in Fig. 8 in the Appendix, and it can change for different field orientations due to differences in the in-plane velocities on the Fermi surface [see Figs. 1(e) and 4].

We assume that $s = 1$ [defined by Eqs. (A9) in the Appendix] for both field orientations and the starting values of the Maki parameters are those from the single band model of $H_{c2}(T)$ in Fig. 2(c).

First, the $H_{c2}(T)$ data are simulated for CaKFe$_4$As$_4$ using parameters corresponding to the $s^\pm$ case [dashed lines Figs. 3(a) and 3(b)], which provide a reasonable representation of the observed behavior for both orientations. However, we find that $H_{c2}(T)$ is best described using $\lambda_{11} = 0.81$, $\lambda_{22} = 0.29$, and $\lambda_{12} = \lambda_{21} = 0.1$ [solid lines in Figs. 3(a) and 3(b)], which is consistent with $s^{\pm}$ pairing. For the later model, the constrained Fermi velocities are $v_1 \sim 380(20)$ meVÅ and $v_2 \sim 54(4)$ meVÅ when $H||c$, and $v_1 \sim 195(20)$ meVÅ and $v_2 \sim 41(4)$ meVÅ when $H||(ab)$ (see Table I). The values of $v_2$ are similar in both orientations, indicative of a strongly warped sheet (see Fig. 4). On the other hand, $v_1$ is larger for $H||c$ and is close to $\sim 360$ meVÅ, reported for the $\alpha$ hole band from ARPES measurements [33]. The band-coupling constants, $\lambda_{ij}$, that describe our data, suggest that the interband scattering due to spin fluctuations is dominated by the intraband effects in CaKFe$_4$As$_4$, which can occur in the presence of strong orbital fluctuations [36]. For $s^\pm$ pairing to overcome $s^\pm$ pairing normally requires the presence of strong disorder, which leads to similar superconducting gaps on different Fermi surfaces [37]. Furthermore, the band coupling constants for the $s^\pm$ case resemble those used to describe a two-band superconductor in the dirty limit [38]. However, CaKFe$_4$As$_4$ is clean, suggesting that disorder effects are negligible. Thus, based on the band-coupling parameters, we conclude that orbital fluctuations may dominate over spin fluctuations.

When the magnetic field lies along the conducting planes, the low-temperature upturn of $H_{c2}(T)$ in Fig. 3(b) cannot be fully captured by only considering the two-band model with large Pauli paramagnetic effects, $\alpha \sim 3.2$. The formation of the FFLO state in a system with a cylindrical Fermi surface requires a large Zeeman energy and a critical Maki’s parameter of $\alpha_c = 4.76$ [2], compared to $\alpha_c = 1.8$ [39] for a three-dimensional Fermi surface. CaKFe$_4$As$_4$ has a complex Fermi surface with two-dimensional cylindrical and highly warped sheets and together with a large value of $\alpha$ creates the conditions for the emergence of an FFLO state [1]. A FFLO state

PHYSICAL REVIEW B 101, 134502 (2020)
We find that the temperature dependence of the upper critical field at low temperatures \( T \) is consistent with the emergence of an FFLO state at low temperatures. The presence of several scattering channels in a multiband system like CaKFe\(_4\)As\(_4\) can increase the upper critical field to a much greater extent than in single gap superconductors, caused by the relative weight of different scattering channels. CaKFe\(_4\)As\(_4\) theoretically has up to six large cylindrical hole bands, (with the equivalent of 50\% hole doping in a 122 iron-based superconductor) providing a large density of states (see Figs. 1(e) and 4 and Ref. [33]) and it can also promote intraband scattering driven by orbital or electron-phonon couplings. On the other hand, the shallow bands in CaKFe\(_4\)As\(_4\) are likely to be involved in the stabilization of the FFLO state. Thus, the temperature dependence of the upper critical field of CaKFe\(_4\)As\(_4\) can reflect the behavior of two dominant superconducting gaps that reside on different sheets of the cylindrical Fermi surface, possibly one on a large hole band and another on a shallow small band. A theoretical work studying the superconducting instabilities in CaKFe\(_4\)As\(_4\) also found two different symmetry representations of the superconducting gap suggesting different pairing interactions, involving both conventional \( s \) wave but also pairing that would lead to additional sign change within the hole and electron pockets [41].

In summary, we have experimentally mapped the upper critical fields of CaKFe\(_4\)As\(_4\) up to 90 T and down to 4.2 K, providing a complete phase diagram for this stoichiometric superconductor. The anisotropy decreases dramatically with temperature, the system becoming essentially isotropic near 4 K. Upper critical fields are extremely large in this system, reaching close to \( \sim 3 T_c \) at the lowest temperature, well above the expectation based on conventional single-band superconductivity. Instead, the temperature dependence of the upper critical field can be described using by a two-band model in the clean limit. The band-coupling constants suggest a dominant orbital pairing over spin fluctuations pairing in CaKFe\(_4\)As\(_4\). Furthermore, for magnetic fields aligned in the conducting plane and due to large Pauli paramagnetic effects, we find that the temperature dependence of the upper critical field is consistent with the emergence of an FFLO state at low temperatures.

In accordance with the EPSRC policy framework on research data, access to the data will be made available [42].

APPENDIX

In this Appendix, we present additional data to support the findings presented in the main paper.

1. Experimental details.

Several high-quality single crystals were used in this study with large residual resistivity ratios $RRR = \rho(300 \text{K})/\rho(36 \text{K}) \sim 14.5$, small $\rho_0$ values of $\sim 9.2 \mu\Omega\text{cm}$ and sharp superconducting transitions with $\Delta T_c \sim 0.1 \text{K}$, as shown in Figs. 5(c) and 1(f). Temperature sweeps were performed at constant magnetic field for different orientations, $H||c$ and $H||(ab)$ to build the high-temperature part of the $H_c2(T)$ phase diagram. Magnetic fields up to 90 T were produced by using current pulses through two different solenoid coils. An example of the magnetic field produced as a function of time is shown in Fig. 6.

2. Determining superconducting coherence lengths

The superconducting coherence lengths can be found in both field orientations near $T_c$ using the Ginzburg-Landau (GL) approach from the equations

$$\xi_{ab}^{GL} = \frac{\Phi_0}{2\pi \mu_0 |\frac{dH_c^a}{dT}|_{T_c}}, \quad \xi_{ab}^{GL} = \frac{\Phi_0}{2\pi \mu_0 |\frac{dH_c^b}{dT}|_{T_c}}, \quad \xi_{c}^{GL} = \frac{\Phi_0}{2\pi \mu_0 |\frac{dH_c^c}{dT}|_{T_c}}$$

where $\Phi_0$ is the magnetic flux quanta, $\mu_0|\frac{dH_c^a}{dT}|_{T_c}$ is the slope near $T_c$ when $H||c$, $\mu_0|\frac{dH_c^b}{dT}|_{T_c}$ is the slope near $T_c$ when $H||(ab)$, and $\xi_{ab}^{GL}$ and $\xi_{c}^{GL}$ are the respective GL coherence lengths.

At the lowest temperature, the coherence lengths are extracted using $\mu_0 H_c^a(T \to 0)$ and the following equations:

$$\xi_{ab} = \frac{\Phi_0}{2\pi \mu_0 H_c^a(T \to 0)}$$

where $\xi_{ab}$ and $\xi_c$ are the coherence lengths in the $(ab)$ plane and along the $c$ axis, and $\mu_0 H_c^a(T \to 0)$ and $\mu_0 H_c^c(T \to 0)$ are the critical fields at the lowest temperature when $H||c$ and $H||(ab)$, respectively (see Fig. 7). Using Eqs. (A2) at different constant temperatures, one can estimate $\xi_{ab} \to \xi_{c}(T)$ and $H_c^a \to H_c^c(T)$, and the anisotropy ratio, $\Gamma$, as shown in Fig. 2(b) in the main text and Fig. 7.
FIG. 5. Transport data of CaKFe₄As₄ as a function of temperature and magnetic field. (a) Estimating the critical temperature, $T_c$, from resistivity against temperature in zero magnetic field (left axis) and from magnetic susceptibility in a small applied field of 5 mT (right axis). The midpoint of the transition, $T_{mid}$, is identified as the peak in the derivative $d\rho/dT$. Linear fits are performed above and below the midpoint transition and the intercepts are defined as $T_{off}$ and $T_{on}$, as labeled in the figure. $T_c$ from susceptibility is defined as the point at which diamagnetism occurs and deviates from the high-temperature background and it is closest to the offset temperature in transport. The critical temperatures used to build the phase diagrams in magnetic field were extracted using $T_{off}$ from the transport data. (b) The estimation of the upper critical field, $H_{c2}$, from resistivity in pulsed magnetic field data measured at constant temperature using the same method as in (a). (c) Resistivity against temperature for different samples of CaKFe₄As₄ between 300 K and 2 K. The superconducting transition is very sharp, with $T_{c,0} = 35.0$ K and width $\Delta T_c = 0.15$ K, values typical for all measured single crystals indicating their high quality. (d) Resistivity data as a function of magnetic field for the sample S1 when $H || (ab)$ at 18 K. The dashed black line shows the linear extrapolation used to obtain the zero-field resistivity at 18 K and the intercept, $\rho_{H \to 0}(T)$, and gradient are shown. Using this method, the extracted values of zero-field resistivity measured at constant temperatures are shown in Fig. 1(f).

3. Depairing current density

Using the coherence length, one can also determine the critical depairing current density of a superconductor, $J_d$. As a function of temperature and magnetic field, this is expressed as [24]

$$J_d(T, H) = \frac{2}{3\mu_0\lambda^2(T)} \sqrt{\frac{\mu_0(H_{c2}^2(T) - H^2)^{1/2} \Phi_0}{6\pi}},$$  \hspace{1cm} (A3)

where $\lambda$ is the superconducting penetration depth and $\Phi_0$ is the magnetic flux quantum. At zero temperature and in no magnetic field, this gives

$$J_d(0, 0) = \frac{2}{3\mu_0\lambda^2(0)} \sqrt{\frac{\mu_0H_{c2}(0)\Phi_0}{6\pi}}. \hspace{1cm} (A4)$$

Substituting $\mu_0H_{c2} = \Phi_0/2\pi\xi^2$, this equation can be rearranged to give

$$J_d(0, 0) = \frac{\Phi_0}{3\sqrt{3}\pi\mu_0\lambda^2(0)\xi(0)}.$$

Previous magnetization reported $\mu_0H_{c2} = 22(1)$ mT [14] when $H || c$ at low temperature which, combined with $H_{c2}$ values reported here, give $\kappa \sim 99(2)$ and $\lambda = 183(6)$ nm. Using $\xi = 1.86$ nm, we find that the depairing current density is $J_d \sim 1.62 \times 10^8$ A/cm², which is among the largest of any known iron-based superconductor.

4. The upper critical fields using a two-band model

To describe the entire temperature dependence of $H_{c2}(T)$ for CaKFe₄As₄, including the upturn below ~10 K for both orientations, we use a two-band model in the clean limit.
the inner coil which generates the extremely high fields lasts overlaying pulsed current though two different coils. The pulse on CaKFe$_4$As$_4$ as a function of temperature. The dashed blue and red lines are linear fits near $T_\text{c}$, whereas for strong intraband coupling $w < 0$ [Figs. 3(a), 3(b), 9(a), and 9(b)]. Intraband pairing could indicate a nonsign changing order parameter ($s^+$) between different Fermi surfaces. However, many iron-based materials are dominated by strong intraband pairing, suggestive of a sign changing order parameter ($s^\pm$).

$U_1$ and $U_2$ are defined as

\[
U_1 = 2e^q\text{Re} \sum_{n=0}^{\infty} \int_{q}^{\infty} \text{d}e^{-u^2} \\
\times \left( \frac{u}{n + 1/2} - \frac{t}{\sqrt{b}} \tan^{-1} \left[ \frac{u\sqrt{b}}{r(n + 1/2) + iab} \right] \right),
\]

(A7)

\[
U_2 = 2e^q\text{Re} \sum_{n=0}^{\infty} \int_{q}^{\infty} \frac{\text{d}e^{-u^2}}{\sqrt{b}} \\
\times \left( \frac{u}{n + 1/2} - \frac{t}{\sqrt{b}} \tan^{-1} \left[ \frac{u\sqrt{b}}{r(n + 1/2) + iab} \right] \right).
\]

(A8)

The variables used for this two-band model, $b, \alpha, q, \eta$, and $s$, are defined as

\[
b = \frac{\hbar^2v^2_{c2}H_{c2}}{8\pi\phi_0\hbar^2T_c^2}, \quad \alpha = \frac{4\mu\phi_0k_B T_c}{\hbar v^2_{c2}},
\]

\[
q^2 = \frac{Q^2\phi_0\epsilon_1}{2\pi H_{c2}}, \quad \eta = \frac{v^2_2}{v^2_1}, \quad s = \frac{e_2}{e_1}.
\]

($v_i$ is the in-plane Fermi velocity of band $i$, $\epsilon_i$ is the mass anisotropy ratio, $\epsilon_i = m^i_2/m^i_1$ is related to the ratio between the gradients near $T_c$ in different field orientations, $s$ is band mass anisotropy between the two bands, and $\gamma = \epsilon^{-1/2}$. Various simulations of upper critical fields using this two-band model are shown in Fig. 8. The slope of $H_{c2}$ near $T_c$ of CaKFe$_4$As$_4$, is $-3.3$ for $H||c$ and $-10.8$ for $H||(ab)$, giving an $\epsilon \sim 1/10$. $Q$ is the magnitude of the FFLO modulation and it is found for a given temperature when $H_{c2}$ is maximal ($dH_{c2}/dQ = 0$). The simulations of $H_{c2}$ for $H||(ab)$ assumed that the bands have the same anisotropy parameter $\epsilon_1 = \epsilon_2 = \epsilon$. Other parameters are estimated based on the fitted values using a single-band model and the velocities are minimized locally to find an optimum solution. This approach was used to infer the presence of either interband or intraband dominated pairings, as described in the main body.

A rescaling of the upper critical field has been performed previously mapping $H_{c2}^\alpha \rightarrow H_{c2}^\alpha \times q_{ab}^{-1/4}$, $\alpha_{ab} \rightarrow \alpha_{ab} \times q_{ab}^{-1/4}$, $b_{ab}^{1/2} \rightarrow \eta_{ab}^{1/2}$ in $U_1$, $\eta_{ab}/\eta_{ab}^{1/4}$ in $U_2$. The values of the $\alpha$ parameters change as $\alpha_{ab} \rightarrow \alpha_{ab} \times |\eta|^{-1/2}$ and $\alpha_{ab} \rightarrow \alpha_{ab} \times |\eta|^{-1/2}$. However, this rescaling has not been used in this study, as the ratio between the Fermi velocities $\eta$ is a variable parameter that can be changed between the two field orientations.

Previous studies on CaKFe$_4$As$_4$ have described the onset upper critical field data up to 60 T using the parameters $\lambda_{11} =$
FIG. 8. Two-band upper-critical-field simulations for different band-coupling parameters and values of \( \eta \). Simulations of the reduced upper critical field \( h \) using the two-band model based on Eqs. (A6)–(A9). The parameters listed in each panel correspond to \( s^\pm \) pairing in (a) and (b) with \( \lambda_{11} = \lambda_{22} = 0, \lambda_{12} = \lambda_{21} = 0.5 \), \( s^\pm \) pairing in (c) and (d) with \( \lambda_{11} = \lambda_{22} = 0.81, \lambda_{12} = \lambda_{21} = 0.5 \), and \( s^{++} \) pairing in (e) and (f) with \( \lambda_{11} = 0.81, \lambda_{22} = 0.29 \), and \( \lambda_{12} = \lambda_{21} = 0.1 \), \( \alpha_1 = 0.95 \) for \( H || c \). For panels (b), (d), and (f) the lower curves (left corners) represent the magnitude of the FFLO modulation, \( Q/(2Q(0)) \).

\[ \lambda_{22} = 0, \lambda_{12} \lambda_{21} = 0.25, \eta = 0.2, \alpha = 0.5, \epsilon = 1/6, \text{and the above rescaling [7].} \]

Using these parameters, we find that the onset upper critical field data (open blue and red symbols) clearly fail to describe the full temperature dependence of the upper critical field of CaKFe\(_4\)As\(_4\), as shown in Figs. 9(a) and 9(b) (blue and red curves). As discussed in the main body of text, we can reasonably describe the upper critical field of CaKFe\(_4\)As\(_4\) using a two-band model with band parameters for the \( s^\pm \) and \( s^{++} \) pairing (see Table I), as shown in Figs. 9(c) and 9(e), respectively. We note here that an FFLO state can be stabilized at low temperatures for \( H || (ab) \) [Figs. 9(c) and 9(e), right axis].

To further test the obtained parameters, we have modelled both the offset and onset critical fields for both field orientations assuming the \( s^\pm \) and \( s^{++} \) pairing. The parameters for the two cases are listed in Table I and the simulations of the upper critical field are shown in Fig. 9. We find that the parameters describing the offset and onset upper critical fields are similar, with small differences found for the \( \alpha \) values, which are slightly larger as the curvature for \( H_{\text{on}} \) is greater as compared with the \( H_{\text{off}} \) case. The velocities for \( H_{\text{on}} \) are also slightly smaller due to the larger slopes near \( T_c \), which scales as \( |dH_c/dT| \propto 1/v^2 \). Using the values for \( H_{\text{off}} \) and \( H_{\text{on}} \), we expected a \( \sim 20\% \) difference in velocities when \( H || c \)

### Table I. The different parameters used for the simulations of the upper critical field (defined either using an offset or onset magnetic field), using a two-band model and considering different pairing symmetries and magnetic field orientations in CaKFe\(_4\)As\(_4\).

| Parameter | \( H || c \) | \( H || (ab) \) | \( H || c \) | \( H || (ab) \) | \( s^\pm \) | \( s^{++} \) | \( H_{\text{off}} \) | \( H_{\text{on}} \) |
|-----------|----------------|----------------|----------------|----------------|------------|------------|-------------|-------------|
| \( \lambda_{11} \) | 0              | 0              | 0.81           | 0.81           | 0         | 0         | 0.81       | 0.81       |
| \( \lambda_{22} \) | 0              | 0              | 0.29           | 0.29           | 0         | 0         | 0.29       | 0.29       |
| \( \lambda_{12} \) | 0.5            | 0.5            | 0.1            | 0.1            | 0.5       | 0.5       | 0.1        | 0.1        |
| \( \alpha_1 \) | 0.95           | 3.1            | 0.5            | 3.2            | 1.5       | 4.2       | 1.0        | 3.5        |
| \( \alpha_2 \) | 0              | 0.7            | 0              | 0              | 0         | 0         | 0          | 0          |
| \( v_1 \) (meVÅ) | 510(20)        | 253(20)        | 380(20)        | 195(20)        | 400(20)   | 215(20)   | 312(20)    | 181(20)    |
| \( v_2 \) (meVÅ) | 40(4)          | 51(5)          | 54(4)          | 41(4)          | 36(3)     | 43(4)     | 44(4)      | 38(4)      |
| \( \eta \) | \( \sim 0.006 \) | \( \sim 0.04 \) | \( \sim 0.02 \) | \( \sim 0.04 \) | \( \sim 0.008 \) | \( \sim 0.04 \) | \( \sim 0.02 \) | \( \sim 0.045 \) |
However, independent of the definition of the upper critical field, the stabilization of an FFLO state in CaKFe₄As₄ for \( H \parallel (ab) \) is realized in both cases.

and a \( \sim 10\% \) difference when \( H \parallel (ab) \), as shown in Table I. However, independent of the definition of the upper critical field, the stabilization of an FFLO state in CaKFe₄As₄ for \( H \parallel (ab) \) is realized in both cases.
