Aphid numbers up, but less than during 2003

Abstract
Brian Lang, extension field specialist, Decorah, has been collecting weekly data on soybean aphids from northeastern Iowa during the past four years. The two tables show the percent of soybean plants with aphids and the average number of aphids per plant. Both of these categories show an aphid population that is slightly larger and occurring on more plants than at this same time last year. However, the population does appear to be much smaller than the outbreak population that we experienced during 2003.

Disciplines
Agriculture | Entomology
Collecting soil samples from fields suspected of being infested with SCN is an alternative to digging soybean roots and looking for adult females and cysts. Soil sampling can be done at any time during the growing season. Soil samples should be submitted to a private soil testing laboratory that offers nematode testing or to the Iowa State University (ISU) Plant Disease Clinic for extraction and counting of SCN eggs. Samples sent to the ISU Plant Disease Clinic should be accompanied by a completed Plant Nematode Sample Submission Form, ISU Extension publication PD 32, available at www.extension.iastate.edu/Publications/PD32.pdf or by calling (515) 294-5247. There is a $15 charge for processing each sample. Detailed instructions on how to collect a representative soil sample for detection of SCN can be found on the back of PD 32 (also see general tips on page 133).

ISU Extension publication IPM 47s, Scouting for Soybean Cyst Nematode, illustrates the recommended procedures for scouting for SCN. Single copies of this publication are available free of charge from county extension offices or from the Extension Distribution Center by calling (515) 294-5247. Additional information about SCN can be found on the Web at www.soybeancyst.info.

Aphid numbers up, but less than during 2003

by Marlin E. Rice, Department of Entomology

Byrnan Lang, extension field specialist, Decorah, has been collecting weekly data on soybean aphids from northeastern Iowa during the past four years. The two tables show the percent of soybean plants with aphids and the average number of aphids per plant. Both of these categories show an aphid population that is slightly larger and occurring on more plants than at this same time last year. However, the population does appear to be much smaller than the outbreak population that we experienced during 2003.

Brian also has seen some soybeans with about 1,000 aphids per plant collected near Fort Atkinson, Winneshiek County. The co-op agronomist who found the infestation reported that only part of the field had significant activity, and the population was estimated to average 400 aphids per plant. Field conditions were very dry in this part of the state, which adds to the concern of early season soybean stress and a good environment for aphid buildup.
