I. INTRODUCTION

The purpose of this investigation is to study the dynamic stability of a typically large (700 to 800 mva) synchronous generator unit with its automatic voltage regulator and governor when connected to an infinite bus through a typically long transmission line. Sets of higher-order differential equations describing the dynamical behavior of the various elements are formulated by state-space methods into sets of first-order equations. In matrix algebra the equations take the form \(x = A \cdot x + D \cdot u\) where \(A\) and \(D\) are the matrices of constant coefficients, \(u\) is the forcing function input vector and \(x\) is the vector representing the state of the system variables. Stability is determined by digital methods in this investigation by insuring that the real part of the eigenvalues of the \(A\)-matrix at various states remains negative.

The voltage at the infinite bus is held at 1.0 per-unit (pu). The generator terminal voltage is iterated to the value needed to supply various power outputs and power factors of operation at the generator terminals. The variations of tie-line reactances and system damping are investigated.

The excitation control system is of a currently standardized type. A derivative power damping signal is used. The effect of varying the voltage regulator parameters and the addition of the governor system on stability are investigated.
Addition of a tie-line control signal to the governor and the extension of the method of investigation to a multi-machine system are discussed briefly.
II. REVIEW OF LITERATURE

For many years the network analyzer was the tool used to compute the steady-state as well as transient stability by establishing new levels of operation in system load flow. These basic concepts, given in Kimbark (19), Crary (9), and by Westinghouse (33) produce conservative results but give a sound background on which to add the refinements present-day computers permit.

Parks (24, 25) established the direct and quadrature component presentation of the synchronous machine. Kilgore (18) and Doherty and Nickle (10) by calculation and testing, clearly defined and established the accuracy of the reactances of the machine. Rankin (26, 27) categorized approaches on per-unit notation. These have helped form the basis for a systematized approach enjoyed in stability studies today.

Stability studies limited by the computation facilities available, were soon enlarged upon. Concordia's work (7) in 1944, studying the steady-state stability of the synchronous machine with the voltage regulator, is a classic reference. Heffron and Phillips (14) in 1952 undertook the study of operation in under-excited regions, made possible by the use of faster, rotating voltage regulators. Improvements in excitation control systems has led to lower short circuit ratio generators with more mega-volt-ampere capacity.
from a given frame size. The excitation control systems which have been developed have been standardized (16) for system stability studies.

Trends mentioned above could only proceed as fast as computer facilities and programs evidenced stability. The November, 1964 Northeast power failure (13) caused new interest and concern in assaying the correctness of programs with respect to interconnected systems. Fortunately computer facilities were available.

Olive (23) in his program in 1965 gave one of the first papers on the problem of detailed programming of transient and steady-state stability permitting 500 machines, 1000 busses, and 1500 lines. Young and Webler (34) and their similar program permitted 250 machines, 1000 busses, and 2000 lines. Both programs contained the machine, control, and system representations deemed needful for these studies. Steady-state stability checks in these programs were accomplished by a step-input perturbation followed by a real-time run of five seconds or more to insure return to stable operation. Certain simplifications in transient stability programming were permissible for steady-state checks but the method of multi-step, swing-curve time solutions along with intermediate iterative load-flow adjustments are fundamental to this method. Many non-linearities can be accommodated. This method is costly but still presently necessary.
A large scale study of the current type in the paper by Lokay and Bolger (22) incorporates transient saliency, saturation, machine and system damping, speed governor system and excitation system with a 660 mw turbine-generator set. Another informative study by Ewart, Landgren, Temoshok, and Walkey (11) investigates a 532 mw cross-compound unit. Damper winding effect is included. Concordia (6) notes in particular the inclusion of damper winding effect is most critically needed in the case of cross-compound generators. Byerly, Skooglund, and Keay (4) in an analog study reported improvement in stability obtained with a power damping control signal fed into the voltage regulator.

VanNess (31) used modern control theory, root loci approach, in his investigation of interconnected systems incorporating the turbine, generator, governor and tie-line controller. Laughton (21) took Heffron's modeling of the synchronous generator and its A-constants combining it into a state-space representation of a 30 mw generator and regulator. The dynamic stability was checked by noting the negativeness of the real part of the eigenvalues of the A-matrix from the state-space formulation of the differential equations.

Undrill (30) extends the work of Laughton analytically and in particular separating out the turbine damping and rotor damping effects. A four-machine system is analyzed
with methods given for extending to a higher number of machines.

Kekela and Firestone (17) present a study of under-excited operation, a problem associated with medium to long length transmission lines.

Schleif and White (28) give an analog study on oscillations prevalent between basically hydro and steam generating areas interconnected by long transmission lines.
III. SYSTEM STABILITY BY EIGENVALUES

Modern control theory (3) has permitted the investigation of stability of differential equations describing a system by means of root locus, Bode, or Nyquist plots, to name a few. Routh criterion approach determines stability by ascertaining the negativeness of the real part of the roots of the higher-order characteristic equation without factoring it.

A. Method of Analysis

The method employed to determine stability is to form the equations interrelating circuit values and motion as a series of first order differential equations. By means of Taylor's expansion, linearization around steady-state operating conditions is made and differential equations formed with the equations interrelated by variables defined as states of the vector space method (2). Placing these equations in matrix algebra notation (5) the required eigenvalues of such a reduced system matrix are the same as the roots of the characteristic equation. The negativeness of the real part of the eigenvalue assures stability; the more negative, the sooner the contribution of the associated term will die out. A complex conjugate root indicates oscillation with the higher frequencies associated with the larger imaginary parts.
B. Formulation of the Equation

In matrix algebra, the equations take the form \( \dot{x} = Ax + Du \) where \( A \) and \( D \) are the matrices of constant coefficients, \( u \) is the forcing function input vector and \( x \) is the vector representing the state of the system variables. In this investigation the stability of the equations was determined by digital methods on an IBM 360/65 using Fortran admitting complex algebra programming. The real part of the eigenvalues of the \( A \)-matrix at various states must remain negative to insure that the solution equation decays to a stable final value as would be obtained in a real-time solution for \( x(t) \). Thus the linearized equations thus formed give a good approximation to the resulting time solutions. It is this piecewise or indirect method of determining stability that is investigated further.

General information concerning the boundaries of stable regions is not gained from this method but the stability limits under a multitude of operating conditions can be accurately determined.

C. Eigenvalue Routine

The correctness of the investigation relies heavily on the eigenvalue solution routine for a non-symmetric matrix by the QR transform by Imad and VanNess (15). This is available as a Share program library routine. The main program
calls this library routine and the eigenvalues only were printed out in real and imaginary parts. Lacking a negative sign, the positive real part of any eigenvalue marks that particular power output and power factor setting, unstable.

The Share program was checked against the Krylov Method for non-symmetric matrices in Faddeeva* and checked to five decimal places. It is known, however, that the QR transform routine is dependent upon the A-matrix itself. The routine was dimensioned at 30 by 30.

D. Extent of the Investigation

A large modern single-shaft steam turbine driven (600 to .700 mw) generator was investigated. It was connected to an infinite bus through a typical long transmission line or tie line. It had an excitation control system and a prime-mover and governor system. The investigation follows Laughton (21) in per-unit on the machine base but varies in five ways:

1. The infinite bus is held at 1.0 pu on the machine base voltage and the effect of regulating by adjusting the generating terminal voltage is noted. Laughton held the terminal voltage at 1.0 pu.

2. The generator is large, typical of present day large units, whereas Laughton's generator was 30 mw.

---

*Faddeeva (12, p. 156).
3. Laughton investigated stability with the voltage regulator and machine only. This investigation includes the prime mover and governor.
4. Effect of varying machine damping, $D$, is included.
5. Effect of varying the tie-line reactance, $X_{\text{line}}$, is included. A Pi-line equivalent network (see Figure 2) is used.

The method of extending the investigation to include a tie-line controller is given; also, Laughton's method of extending the study to a multi-machine system is included.
IV. SYNCHRONOUS GENERATOR

The phasor diagram covering the Parks direct and quadrature-axis representation of the synchronous generator (25, 26) is given in Figure 1. It is convenient to include the tie-line connecting the generator to the infinite bus in the same analysis. The equivalent adjusted Pi-line representation* per Figure 2 has been made by separate calculation.

The list of symbols and Fortran equivalent names are given in the Appendix A. The actual per-unit, (pu) values on the machine base used are found in Programs 1 and 2 of the Appendix C. It should be noted that since power factor is the independent variable and with generator power output held constant, pu current equals pu power output divided by the product of power factor times the pu terminal voltage. Rated three-phase mva and rated line-to-line terminal voltage are the two machine bases, both taken as 1.0 pu. Rated full-load power in pu is then 0.9 pu for a 0.90 power factor machine and must be so read into the program. The infinite bus voltage, $V_b$, is held at 1.0 pu as long as the terminal voltage, $V_t$, does not fall below 0.8 pu to maintain this condition. $V_t$-terminal must be determined by iterating with each change in power factor.

*Westinghouse Electric Corporation (33, p. 44).
Figure 1. Phasor diagram of generator and tie-line
Figure 2. Model of transmission line for the calculation of the terminal voltage of the generator
It should be noted that the tie-line or transmission line inductive reactance often identified by x-line rather than $x_e$ refers to its equivalent pu reactance on the machine base.

The effect of change of speed on generated voltages due to the damper winding has been assumed as negligible in this analysis. Balanced loads are assumed.

A. Operating Matrix Equations

When a Taylor-series expansion is formed about any operating point, for each of the equations (54-58), the resulting linear perturbation relationships of the first order may be expressed as in Equation 1. This matrix equation summarizes the relationship between all machine and system variables where the inputs are $\Delta T_m$ through the prime mover and $\Delta V_{fd}$ through the excitation system. The controlled machine variables $\Delta \delta$, $\Delta V_t$ and $\Delta I$, and all time-derivative quantities are in the first two equations. (See following page for Equation 1.)

B. Reduced System A-constants

Equation 1 has the matrix form.

$$ F = MG $$

or, in the expanded form.
\[
\begin{align*}
\Delta T_m &= M_p^2 + D_p \\
\Delta Y_{ld} &= 1 \\
\Delta Y_{id} &= 1 \\
\Delta V_b &= \frac{\Delta V_t}{V_t} \\
\Delta V_b \cos L &= 1 \\
\Delta V_b \sin L &= 1 \\
\Delta r_d &= 1 \\
\Delta r_q &= 1 \\
\Delta x_d &= 1 \\
\Delta x_q &= 1 \\
(1 + \gamma_p) &= 1 \\
\gamma_p(x_d - x_d^*) &= 1 \\
\end{align*}
\]
and therefore the variables not of interest, \( \Delta V_d \) to \( \Delta \psi_q' \), may be eliminated by matrix reduction, yielding

\[
\begin{bmatrix}
\Delta T_m \\
\Delta V_{fd} \\
0 \\
0 \\
\end{bmatrix}
= 
\begin{bmatrix}
M_1 - M_2 M_4^{-1} M_3 \\
\cdot \\
\cdot \\
\cdot \\
\end{bmatrix}
\cdot 
\begin{bmatrix}
\Delta \delta \\
\Delta \psi_{fd} \\
\Delta V_t \\
\Delta I \\
\end{bmatrix}
\] (3)

Writing, for purposes of brevity, \( R_d = r_d + r_e \), \( X_d = x_d + x_e \) and continuing for \( R_q' \), \( X_q' \), Equation 4 can be expanded as

\[
\begin{bmatrix}
\Delta T_m \\
\Delta V_{fd} \\
0 \\
0 \\
\end{bmatrix}
= 
\begin{bmatrix}
M_1 - M_2 M_4^{-1} M_3 \\
\cdot \\
\cdot \\
\cdot \\
\end{bmatrix}
\cdot 
\begin{bmatrix}
\Delta \delta \\
\Delta \psi_{fd} \\
\Delta V_t \\
\Delta I \\
\end{bmatrix}
\] (4)

\[
\begin{bmatrix}
\Delta T_m \\
\Delta V_{fd} \\
0 \\
0 \\
\end{bmatrix}
= 
\begin{bmatrix}
M_1 - M_2 M_4^{-1} M_3 \\
\cdot \\
\cdot \\
\cdot \\
\end{bmatrix}
\cdot 
\begin{bmatrix}
\Delta \delta \\
\Delta \psi_{fd} \\
\Delta V_t \\
\Delta I \\
\end{bmatrix}
\] (5)
where the relationships summarized by the constants $A_1 - A_9$, are given in Appendix B. These are the $A$-constants found in Laughton (21) which also are directly related to constants formed by Heffron and Phillips (14). Laughton found that eliminating resistances introduced a five percent error. With a fast computer the added correctness warranted retaining all resistances.

The matrix reduction was done algebraically to confirm Laughton's $A$-constants. It can be done by digital matrix reduction as well, switching rows so that the principal diagonal contains no zeros.

C. Feedback Control Scheme

The operating matrix Equation 1 and the reduced system matrix Equation 5 represent an open-loop system of one machine connected to an equivalent infinite bus system with two arbitrary forcing functions, the excitation system and the prime mover. Addition of further regulating equipment may be made with the field control responding to changes in terminal voltage, current and rotor angle. Additional equations, including the governor are

\[ \Delta V_{fd} = -G_1(p)\{\Delta V_t + G_2(p)\Delta I + G_3(p)\Delta \delta\} \]  

(6)

and

\[ \Delta T_m = -G_4(p)\Delta \delta \]  

(7)
where $G_1(p), \ldots G_4(p)$ are the transfer functions of these respective sub-systems.

The block diagram of the above control scheme and machine with feed-back loops is given in Figure 3.

D. State-space Equations

It is now possible to rearrange the Equation 5 by state-space methods (21) to the required set of first-order equations. For linear constant-coefficient systems, the equations take the form

$$\dot{X} = AX + Du$$ \hspace{1cm} (8)

A first-order vector differential equation, where $A$ and $D$ are matrixes of constant coefficients, $u$ is the forcing-function inputs and $x$ the vector representing the state of the system variables.

Letting

$$x_1 = \Delta \delta$$

$$x_2 = \dot{x}_1 = \Delta \dot{\delta}$$

$$x_3 = \Delta \phi_{fd}$$

and control input variables,

$$u_1 = \Delta v_{fd}$$

$$u_2 = \Delta T_m.$$
Figure 3. Block diagram of synchronous generator connected to an equivalent power system with multi-loop machine feedback control system.
Equation 5 becomes

\[
\begin{pmatrix}
  \dot{x}_1 \\
  \dot{x}_2 \\
  \dot{x}_3
\end{pmatrix} =
\begin{pmatrix}
  0 & 1 & 0 \\
  A_1 \frac{1}{M} & -D & \frac{A_2}{M} \\
  -A_3 & 0 & -\frac{1}{\tau dz}
\end{pmatrix}
\begin{pmatrix}
  x_1 \\
  x_2 \\
  x_3
\end{pmatrix} +
\begin{pmatrix}
  0 \\
  0 \\
  \frac{-1}{A_4 \tau dz}
\end{pmatrix}
\begin{pmatrix}
  u_1 \\
  u_2
\end{pmatrix}
\]  

(9)

The output may also be represented by

\[ Y = B x \]  

(10)

in which case Equation 5 can be expanded by substituting

\[ y_1 = \Delta V_t, y_2 = \Delta I \]  

giving

\[
\begin{pmatrix}
  y_1 \\
  y_2
\end{pmatrix} =
\begin{pmatrix}
  A_5 & 0 & A_6 \\
  A_7 & 0 & A_8
\end{pmatrix}
\begin{pmatrix}
  x_1 \\
  x_2 \\
  x_3
\end{pmatrix}
\]  

(11)

The stability of the system by Equation 5 is assured when the forcing functions \( u \) are finite values, only if all the eigenvalues of the coefficient matrix \( A \) as found from

\[ \text{Det}(A - \lambda I) = 0 \]  

(12)

have negative real parts.
E. Damping

The system damping including that of the damper winding circuit is investigated at two values, \( D = 2 \) and \( D = 3 \). It does not include the effect of rotor damping currents on the generated voltage.

Concordia (6) states that except for the case of cross-compound generator sets, omitting the damper winding (or amortisseur winding) has little effect on steady-state stability. Likewise Laughton (21) states damping is of no great importance as to locating the stability limit.

Undrill (30) treats the damper winding separately with speed voltage effects. The necessity and accuracy of this addition is an area for separate study.

F. Saturation

Generator saturation manifests its effect in two ways, in the transient reactance and in the excitation requirements.

1. Reactances

Kilgore (18) has published the effect of saturation in depth. Based on Kilgore's data the transient reactance used for \( x_d' \) was taken at 0.93 times the saturated transient reactance at 1.0 pu current. All other values of reactances and open-circuit field time constants were based on unsaturated conditions.
2. **Excitation requirements**

The generator saturation effect is taken from Young and Webler (34). The equation for the increase in excitation voltage, $\Delta E_I$ per Figure 1 is given by

$$\Delta E_I = a_G (E_P - 0.8)$$

where $E_P$ is the voltage behind Potier reactance $x_P$ and $a_G$ and $b_G$ are constants derived from taking two points on the saturation curve, Figure 4.

$a_G$ and $b_G$, calculated separately and found to be 0.035 and 7.358 respectively, appear in this form in Program 1 of Appendix C. $E_P$ is calculated as $E_P = V_T + Ix_P$ in complex form. Finally $\Delta E_I$ is added to $E_{fd}$ giving the saturated or actual pu field voltage needed.

Generator field heating is a possible limitation on over-excited operation with the infinite bus held at 1.0 pu voltage.

G. **Tie-line Reactance**

The tie-line or transmission line is an equivalent Pi-representation given by Figure 2. The bus voltage is held at 1.0 pu of generator terminal voltage as long as the generator terminal voltage does not fall below 0.8 pu. By iteration, in Program 1, Appendix C, the terminal voltage is adjusted to give $V_D = 1.0$ pu, without tap-change, before
Figure 4. Representation of saturation of generator
further calculations are made.

Two values of tie-line impedance were investigated. Since the value of the tie-line reactance has a great effect on stability, tabulations are all identified by the tie-line reactance used, namely, $X_{\text{LINE}} = 0.414 \text{ pu}$ or $X_{\text{LINE}} = 0.718 \text{ pu}$. These are Pi-line adjusted values. Programs 1 and 2 of Appendix C input values that are associated with the lower and higher tie-line reactances respectively. The use of shunt capacitors could easily be added as a separate study.
V. EXCITATION SYSTEM

The Institute of Electrical and Electronics Engineers power generating excitation systems subcommittee has formulated and reported recommended computer representations for four major types of excitation systems (16). The constants and symbols used with block diagrams, per unit notation, and exciter saturation representation used below follow this committee report.

A. Type 1 System

Figure 5 is the block diagram of the excitation system. One of the signals initially summed is the time derivative of electric power. The state-space equations for the type 1 system will be developed and then the power signal treated separately.

Following Anderson and Fouad (1) the type 1 system may be redrawn as Figure 6.

Now

\[
\frac{V_F}{V_E} = \frac{G_2G_3}{1 + G_3H_1 + G_2G_3H_2}
\]

(14)

where

\[
V_E = V_{REF} + V_S - G_1V_T
\]

Substituting and rearranging
Figure 5. Type 1 excitation system block diagram
Figure 6. Simplified block diagram of type 1 excitation system

Where

\[ G_1 = \frac{1}{1 + ST_R} \]

\[ G_2 = \frac{K_A}{1 + ST_A} \]

\[ G_3 = \frac{1}{K_E + ST_E} \]

\[ H_1 = S_E \]

\[ H_2 = \frac{SK_F}{1 + ST_F} \]
\[ \frac{V_F}{V_E} = \frac{K_A(1 + ST_F)}{(1 + ST_A)(K_E + ST_E)(1 + ST_F) + S_E(1 + ST_A)(1 + ST_F) + K_A K_F S} \]  

(15)

The right-hand side denominator, call it \( \phi(s) \), is the characteristic equation. Rearranging

\[ \phi(s) V_F = K_A(1 + ST_F) V_E \]  

(16)

where

\[ \phi(s) = T_A T_E F S^3 + \left[ K_E T_A T_F + T_E (T_A + T_F) + S_E T_A T_F \right] S^2 + \left[ (K_E + S_E) (T_A + T_F) + T_E + K_A K_F \right] S + (K_E + S_E) \]  

(17)

dividing by \( (T_A T_E F) \) and taking the inverse Laplace transform gives

\[ v_f + a_1 v_f + a_2 v_f + a_3 v_f = b_0 v_e + b_1 v_e + b_2 v_e + b_3 v_e \]

where

\[ a_1 = \frac{T_E (T_A + T_F) + T_A T_F (K_E + S_E)}{T_A T_E F} \]

\[ a_2 = \frac{(K_E + S_E) (T_A + T_F) + T_E + K_A K_F}{T_A T_E F} \]

\[ a_3 = \frac{K_E + S_E}{T_A T_E F} \]  

(18)
\[ b_0 = b_1 = 0 \]
\[ b_2 = \frac{K_A}{T_A T_E} \]
\[ b_3 = \frac{K_A}{T_A T_E T_F} \]

Rewriting Equation 18 terms of \( p \)-operator as

\[
(p^3 + a_1 p^2 + a_2 p + a_3) v_f =
\]
\[(b_0 p^3 + b_1 p^2 + b_2 p + b_3) v_e \]

or

\[
p^3(v_f - b_0 v_e) + p^2(a_1 v_f - b_1 v_e) + p(a_2 v_f - b_2 v_e) + (a_3 v_f - b_3 v_e) = 0 \tag{19}\]

and rearranging after dividing by \( p^3 \) we get

\[
v_f - b_0 v_e = \frac{1}{p}(b_1 v_e - a_1 v_f) + \frac{1}{p^2}(b_2 v_e - a_2 v_f) + \frac{1}{p^3}(b_3 v_e - a_3 v_f) \tag{20}\]

calling \( x_4 = v_f - b_0 v_e \), following the underscoring brackets
\[ x_5 = x_4 + (a_1 v_f - b_1 v_e) \]
\[ x_6 = x_5 + (a_2 v_f - b_2 v_e) \]  \hspace{1cm} (21)

To place the equations in state-space form \( \dot{x} = A x + D u \), noting that \( v_f = x_4 + b_0 v_e \) now

\[ x_6 = \frac{1}{p} (b_3 v_e - a_3 v_f) \]
\[ p x_6 = b_3 v_e - a_3 v_f \]  \hspace{1cm} (22)
\[ x_6 = b_3 v_e - a_3 (x_4 + b_0 v_e) \]
\[ x_6 = -a_3 x_4 + (b_3 - a_3 b_0) v_e \]

and

\[ x_5 = \frac{1}{p} (b_2 v_e - a_2 v_f + x_6) \]
\[ x_5 = b_2 v_e - a_2 (x_4 + b_0 v_e) + x_6 \]  \hspace{1cm} (23)
\[ x_5 = -a_2 x_4 + x_6 + (b_2 - a_2 b_0) v_e \]

and

\[ x_4 = \frac{1}{p} (b_1 v_e - a_1 v_f) + x_5 \]
\[ x_4 = b_1 v_e - a_1 (x_4 + b_0 v_e) + x_5 \]  \hspace{1cm} (24)
\[ x_4 = -a_1 x_4 + x_5 + (b_1 - a_1 b_0) v_e \]

In matrix form \( \dot{x} = A x + D u \), noting \( b_0 = b_1 = 0 \)
\[
\begin{bmatrix}
\dot{x}_4 \\
\dot{x}_5 \\
\dot{x}_6 \\
\dot{x}_7 \\
\end{bmatrix} =
\begin{bmatrix}
-a_1 & 1 & 0 \\
-a_2 & 0 & 1 \\
-a_3 & 0 & 0 \\
0 & 0 & 0 \\
\end{bmatrix}
\begin{bmatrix}
x_4 \\
x_5 \\
x_6 \\
x_7 \\
\end{bmatrix}
\begin{bmatrix}
\dot{x}_4 \\
\dot{x}_5 \\
\dot{x}_6 \\
\dot{x}_7 \\
\end{bmatrix}
\begin{bmatrix}
b_1 - a_1 b_0 \\
b_2 - a_2 b_0 \\
b_3 - a_3 b_0 \\
-1/T_R \\
\end{bmatrix}
\begin{bmatrix}
v_e \\
v_e \\
v_e \\
v_e \\
\end{bmatrix}
\]

Addition of the three "inputs"

\[
V_E = \frac{-V_T}{1 + ST_R} + V_{REF} + V_S
\]

does not change the matrix to

\[
\begin{bmatrix}
\dot{x}_4 \\
\dot{x}_5 \\
\dot{x}_6 \\
\dot{x}_7 \\
\end{bmatrix} =
\begin{bmatrix}
-a_1 & 1 & 0 & (b_1 - a_1 b_0) \\
-a_2 & 0 & 1 & (b_2 - a_2 b_0) \\
-a_3 & 0 & 0 & (b_3 - a_3 b_0) \\
0 & 0 & 0 & -1/T_R \\
\end{bmatrix}
\begin{bmatrix}
x_4 \\
x_5 \\
x_6 \\
x_7 \\
\end{bmatrix}
\begin{bmatrix}
0 \\
0 \\
0 \\
-1/T_R \\
\end{bmatrix}
\]

where \( v = -v_t + v_{ref} + v_s \).
B. Power Damping Signal

The lower blocks in Figure 5 inputs a damping power signal. The time constant $T_R$ is zero. This alters as follows:

$$V_E = -V_T + V_{REF} + \frac{K_{SKD} P}{1 + ST_D}$$

from which

$$v_e + T_D \dot{v}_e = -v_t + v_{ref} + K_{TKD} \frac{dP}{dt} \frac{d\delta}{dt}$$

and

$$v_e = \frac{-v_e - v_t + v_{ref}}{T_D} + \frac{K_{TKD}}{T_D} \frac{dP}{dt} \frac{d\delta}{dt}$$  \hspace{1cm} (27)

Now

$$\frac{d\delta}{dt} = x_2 = x_1 = \Delta \delta$$

from the machine state-space equation and $\frac{dP}{d\delta}$ can be calculated from Concordia *

$$P = \frac{E V_T}{x_d'} \sin \delta + \left( \frac{1}{x_q} - \frac{1}{x_d'} \right) \frac{V_T^2}{2} \sin 2\delta$$

and

$$\frac{dP}{d\delta} = \frac{E V_T \cos \delta}{x_d'} + \left( \frac{1}{x_q} - \frac{1}{x_d'} \right) \frac{V_T^2}{2} \cos 2\delta$$  \hspace{1cm} (28)

* Concordia (8, p. 38).
where
\[ E = \psi_d + x'_d i_d. \]

The regulator can now be combined with the machine. \( K_A \) inputs the signals to excitation system level similar to Laughton's* \( G_1 \) function. In this machine a generator field voltage of 274 volts produces 1.0 per unit generator volts on the air-gap line. This is the \( K_2 \) scaling factor, per Laughton.*

**C. Saturation**

Figure 7 shows the meaning of the saturation function and how it is actually calculated. In the same manner as Equation 13 was used to calculate \( \Delta E_I \) for the generator saturation, in a like manner \( S_E \) can be calculated from two values from the exciter saturation curve or equivalent data.

\[ S_E = A_E (e^{B_E (E_{FD} - 8)}) \quad \text{(29)} \]

In this exciter \( A_E \) was calculated to be 0.235 and \( B_E \) was calculated to be 0.214. \( S_E \) was limited to give a maximum of 0.835 in the program for cases of overexcited operation.

*Laughton (21, p. 335).
Figure 7. Calculation of exciter saturation

\[ S_E = f(E_{FD}) = \frac{A - B}{B} = \frac{A}{B} - 1 \]
D. State-space Equations

Equation 30 gives the resulting state-space matrix formulation. Note $b_0 = b_1 = 0$. 
The document contains a matrix representation with variables and equations. The matrix is labeled as $A$ and is defined as:

\[
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

The variables $x_1, x_2, x_3, x_4, x_5, x_6, x_7$ are defined as:

\[
\begin{align*}
  x_1 &= \Delta \delta \\
  x_2 &= \Delta \dot{\delta} \\
  x_3 &= \Delta \delta_{fd} \\
  x_4 &= \Delta V_f \\
  x_5 &= \Delta V_t \\
  x_6 &= \Delta v \\
  x_7 &= \Delta V_e
\end{align*}
\]

The matrix $A$ is multiplied by $D$ and $U$ to yield $\Delta T_M$ and $\Delta V$ where $V = -\Delta V_t + \Delta V_{ref}$.

$x_4, x_5, x_6, x_7$ derive from state formulation of type I excitation system.
VI. GOVERNOR SYSTEM

The single-shaft steam turbine driving the generator is given by block diagram representation in Figure 8 which includes the details of the prime mover and governor. State-space equations are formulated. The addition of an auxiliary control signal, tie-line control, is treated separately. Gain $K_1$ has been divided by rated mw to place it in per-unit level.

A. Single-shaft Governor Representation

State-space variable approach from Anderson and Fouad (1) will be followed. The steam system dynamics includes steam and reheat time constants and the fraction of reheat. The governor includes water hammer correction, the servo valve motor, and control system time constants. The block diagram of the single-shaft governor is given in Figure 8.

B. State-space Equations

1. Steam-system dynamics

The transfer function of the steam system Figure 9 by parallel programming is:

$$G(s) = \frac{1 + K_2 T_5 S}{(1 + T_4 S)(1 + T_5 S)}$$

By partial fraction expansion
Figure 8. Block diagram of governor system

- \( T_1 \): Control system time constant
- \( T_2 \): Water hammer correction
- \( T_3 \): Servo valve motor
- \( T_4 \): Steam system time constant
- \( T_5 \): Reheat Steam system time constant
- \( K_f \): Overall gain (per unit power/radian/second)
- \( K_2 \): Fraction of steam reheated
\[ G(s) = \frac{A}{1 + T_4 s} + \frac{B}{1 + T_5 s} \]  \hspace{1cm} (32)

Solving for \( A \) and \( B \)

\[ A = \frac{T_4 - K_2 T_5}{T_4 - T_5} \]

\[ B = \frac{T_5 (1 - K_2)}{T_5 - T_4} \]

and substituting in Equation 32 gives

\[ G(s) = \frac{(T_4 - K_2 T_5)/T_4 (T_4 - T_5)}{s + 1/T_4} + \frac{(1 - K_2)/(T_5 - T_4)}{s + 1/T_5} \]  \hspace{1cm} (33)

calling

\[ A' = (T_4 - K_2 T_5)/T_4 (T_4 - T_5) \]

\[ B' = (1 + K_2)/(T_5 - T_4) \]

the branches take the forms

\[ \frac{u}{x} = \frac{A'}{s + 1/T_4} \]

and

\[ \frac{u}{x} = \frac{B'}{s + 1/T_5} \]

Combining as in Figure 10 the state-space variables are:

\[ x_8 = \frac{-1}{T_4} x_8 + u \]
\[ x_9 = \frac{1}{T_5} x_9 + u \]

and

\[ x = A' x_8 + B' x_9 \]  \hspace{1cm} (34)

2. **Governor control system and servo valve**

The transfer function of the governor itself, Figure 8 by parallel programming is:

\[ G(s) = \frac{K_1 (1 + T_2 s)}{(1 + T_1 s)(1 + T_3 s)} \]  \hspace{1cm} (35)

By partial fraction expansion

\[ G(s) = \frac{B_1}{1 + T_1 s} + \frac{B_2}{1 + T_3 s} \]  \hspace{1cm} (36)

Solving for \( B_1 \) and \( B_2 \)

\[ B_1 = \frac{K_1 (T_1 - T_2)}{(T_1 - T_3)} \]

\[ B_2 = \frac{K_1 (T_3 - T_2)}{(T_3 - T_1)} \]

Substituting in Equation 36 gives

\[ G(s) = \frac{K_1 (T_1 - T_2)/T_1 (T_1 - T_3)}{S + 1/T_1} + \frac{K_1 (T_3 - T_2)/T_3 (T_3 - T_1)}{S + 1/T_3} \]  \hspace{1cm} (37)

calling
\[ B_1' = K_1(T_1 - T_2)/T_1(T_1 - T_3) \]
\[ B_2' = K_1(T_3 - T_2)/T_3(T_3 - T_1) \]

Combining as per Figure 11 the state-space variables are

\[
\begin{align*}
\dot{x}_{10} &= -\frac{1}{T_1} x_{10} + u_{in} \\
\dot{x}_{11} &= -\frac{1}{T_3} x_{11} + u_{in} \\
u' &= B_1' x_{10} + B_2' x_{11} \tag{38}
\end{align*}
\]

Combining the two transfer functions per Figure 12

\[
u_{in} = -\Delta \delta + \omega_s = \omega_s - x_2 \tag{39}\]

where \( x_2 = \Delta \delta \); \( \omega_s \) = auxiliary signal. Substituting in the Equation

\[
\begin{align*}
\dot{x}_{10} &= -\frac{1}{T_1} x_{10} + x_2 + \omega_s \\
\dot{x}_{11} &= -\frac{1}{T_3} x_{11} - x_2 + \omega_s
\end{align*}
\]

Solving for \( x_8 \) and \( x_9 \)

\[
\begin{align*}
u_\Delta &= P_\Delta - u'_\Delta \\
&= P_\Delta - B_1' x_{10} - B_2' x_{11} \tag{40}
\end{align*}
\]

where subscript \( \Delta \) refers to a small increment of that variable.
\[ x_8 = -\frac{1}{T_4} x_8 + u_\Delta \]
\[ = -\frac{1}{T_4} x_8 - B_1 x_{10} - B_2 x_{11} + P_{\Delta o} \]

and

\[ x_9 = -\frac{1}{T_5} x_9 - B_1 x_{10} - B_2 x_{11} + P_{\Delta o} \] (41)

State-space equations for governor system are

\[ x_8 = -\frac{1}{T_4} x_8 - B_1 x_{10} - B_2 x_{11} + P_{\Delta o} \]
\[ x_9 = -\frac{1}{T_5} x_9 - B_1 x_{10} - B_2 x_{11} + P_{\Delta o} \]
\[ x_{10} = -\frac{1}{T_1} x_{10} - x_2 + \omega_s \] (42)
\[ x_{11} = -\frac{1}{T_3} x_{11} - x_2 + \omega_s \]

The final combined state-space formulation of generator, excitation system and governor control system is given in Equation 43.
\[
\frac{(1 + K_2 T^S) X}{(1 + T_4 S)(1 + T_5 S)}
\]

Shaft power

Figure 9. Transfer function of steam system

Figure 10. State-space diagram of steam system

Figure 11. State-space diagram of control system and servo valve
Figure 12. State space diagram of governor system
VII. TIE-LINE CONTROLLER

For area control, a tie-line controller can be added. The following method by VanNess gives the desired additional equations.

A. Tie-line Controller Representation

Tie-line, load frequency, control signals can be fed into the governor input as auxiliary signals, see Figure 13. VanNess' (31) speed-droop characteristic 1/R is separated from \( K_1 \) gain in the previous discussion. \( P_C \) is the reset control signal.

B. State-space Equations

The additions to the previous matrix equations by the controller are given by

\[
\begin{align*}
\dot{X}_R &= K_R X_P \\
T_R X_P + X_P &= P_C \\
X_P &= \frac{P_C}{T_R} - \frac{X_P}{T_R} \\
T_G X_G + X_G &= -K_P P_{CA} - \frac{\omega}{R} - X_R; \quad \omega = x_2 \\
X_G &= -\frac{X_G}{T_G} - \frac{X_R}{T_G} - \frac{x_2}{R T_G} - \frac{K_P P_{CA}}{T_G}
\end{align*}
\]
These additions to the state-space formulation are given by Equation 47.
Figure 13. Block diagram of addition of tie-line controller

\[
\begin{bmatrix}
\dot{5} \\
\dot{X_R} \\
\dot{X_P} \\
\dot{X_G}
\end{bmatrix} = \begin{bmatrix}
1 & & & \\
& K_R & & \\
& -\frac{1}{T_{KR}} & & \\
-\frac{1}{R T_G} & -\frac{1}{T_G} & -\frac{1}{T_G} & \\
\end{bmatrix} \begin{bmatrix}
\omega \\
X_R \\
X_P \\
X_G
\end{bmatrix} + \begin{bmatrix}
0 \\
0 \\
-\frac{1}{T_{KR}} \\
\frac{1}{R T_G} - \frac{1}{T_G} \frac{K_P}{T_G}
\end{bmatrix} \begin{bmatrix}
P_{CA} \\
P_C
\end{bmatrix}
\]

\[ (47) \]
VIII. MULTI-MACHINE PROBLEM

The analysis can be extended to cover two or more machines with the use of matrix algebra. Undrill (30) uses the terminal voltage of one machine as reference. Laughton (21) uses a separate infinite busbar reference axis. See Figure 14. The extension to the two machines is included for completeness following Laughton.

A. n-Machine Analysis

The equations which relate the machine variables and acceleration are

\[ v_{qi} = V_{ti} \cos \delta_{ii} \]

\[ v_{di} = V_{ti} \sin \delta_{ii} \]  

(48)

where \( i = 1, 2, \ldots n \) (for 2 machines, \( n = 2 \)).

Now the armature current of a generator is a function of all the other armature currents, it is related to its direct and quadrature reference frame and the system reference axis herein called \( V_b \) for simplicity.

Currents are defined \( I_i = a_i + jb_i \) with

\[ I_i^2 = a_i^2 + b_i^2 \]  

(49)

where \( a_i \) and \( b_i \) are variables satisfying network laws.

Now matrix equations for node-voltage network approach
Figure 14. Phasor diagram of a two-machine system
are \( I = Y V \) where \( Y \) = network node admittance matrix and \( V \) the matrix of terminal voltages. Defining \( Y = G - jB \) and \( V = e + jf \):

\[
a_i + jb_i = \sum_{m=1}^{n} (G_{im} - jB_{im})(e_m + jf_m),
\]

where

\[
e_m = V_{tm} \cos(\delta_m - \delta_{lm})
\]

and

\[
f_m = V_{tm} \sin(\delta_m - \delta_{lm})
\]

therefore the final system equations are

\[
a_i = \sum_{m=1}^{n} \{G_{im}V_{tm} \cos(\delta_m - \delta_{lm}) + B_{im}V_{tm} \sin(\delta_m - \delta_{lm})\}
\]

\[
b_i = \sum_{m=1}^{n} \{G_{im}V_{tm} \sin(\delta_m - \delta_{lm}) - B_{im}V_{tm} \cos(\delta_m - \delta_{lm})\}
\]

(50)

The operating point may be selected by means of an iterative matrix analysis (29) and perturbation relationships developed about this point as before.

For two machines on an infinite bus, the perturbation equations in matrix form are shown in Equation 51.

The constants \( k_{ij} \) in Equation 51 are the constants involved in the perturbation equations corresponding to Equation 50; thus
\[
\begin{align*}
M_{m}^2 &= D_{m}p \\
M_{q}^2 &= D_{q}p \\
\theta &= \gamma \rho \rho \\
\gamma &= \gamma_{el} - \gamma_{i}
\end{align*}
\]

\[
\begin{bmatrix}
& & & & & & & & & \\
& & & & & & & & & \\
& & & & & & & & & \\
& & & & & & & & & \\
& & & & & & & & & \\
& & & & & & & & & \\
& & & & & & & & & \\
& & & & & & & & & \\
& & & & & & & & & \\
& & & & & & & & & \\
\end{bmatrix}
\]

\[
\begin{align*}
\sin \theta_{11} &= 1 \\
\cos \theta_{11} &= 1 \\
\sin \theta_{12} &= 1 \\
\cos \theta_{12} &= 1 \\
\end{align*}
\]

\[
\begin{align*}
K_{22} &= K_{23} \\
K_{12} &= K_{13} \\
\end{align*}
\]

\[
\begin{align*}
\sin \theta_{22} &= 1 \\
\cos \theta_{22} &= 1 \\
\sin \theta_{23} &= 1 \\
\cos \theta_{23} &= 1 \\
\end{align*}
\]

\[
\begin{align*}
K_{42} &= K_{43} \\
K_{32} &= K_{33} \\
\end{align*}
\]
\[ \Delta a_j = \sum_k \left[ G_{jk} \cos(\delta_k - \delta_{Ik}) + B_{jk} \sin(\delta_k - \delta_{Ik}) \right] \Delta V_{tk} \]
\[ + V_{tk} \left[ -G_{jk} \sin(\delta_k - \delta_{Ik}) + B_{jk} \cos(\delta_k - \delta_{Ik}) \right] (\Delta \delta_k - \Delta \delta_{Ik}) \]
\[ \Delta b_j = \sum_k \left[ G_{jk} \sin(\delta_k - \delta_{Ik}) - B_{jk} \cos(\delta_k - \delta_{Ik}) \right] \Delta V_{tk} \]
\[ + V_{tk} \left[ G_{jk} \cos(\delta_k - \delta_{Ik}) + B_{jk} \sin(\delta_k - \delta_{Ik}) \right] (\Delta \delta_k - \Delta \delta_{Ik}) \]
\[ j, k = 1, 2 \]

or in matrix form
\[
\begin{bmatrix}
\Delta a_1 \\
\Delta b_1 \\
\Delta a_2 \\
\Delta b_2
\end{bmatrix}
= 
\begin{bmatrix}
k_{11} & k_{12} & k_{13} & k_{14} \\
k_{21} & k_{22} & k_{23} & k_{24} \\
k_{31} & k_{32} & k_{33} & k_{34} \\
k_{41} & k_{42} & k_{43} & k_{44}
\end{bmatrix}
\begin{bmatrix}
\Delta V_{t1} \\
\Delta V_{t2} \\
\Delta V_{t3} \\
\Delta V_{t4}
\end{bmatrix}
\]

The coefficient matrix can be reduced by means of the Kron\(^*\) reduction the same as for a single machine connected to an infinite bus. Writing the coefficient matrix in Equation 51 as
\[ M = \begin{bmatrix} M_1(p) + M_2 & M_3(p) + M_4 \\
M_5 & M_6 \end{bmatrix} \]

where \( M_1(p) \) and \( M_3(p) \) contain terms involving the differential

\(^*\) Kron (20, p. 378).
operator \( p \) only. The reduced coefficient matrix representing the system of interest, represented by the first eight variables is

\[
M_{\text{reduced}} = \{M_1(p) - M_3(p)M_6^{-1}M_5\} + \{M_2 - M_4M_6^{-1}M_5\} \quad (54)
\]

The term in the last bracket and \( M_3(p)M_6^{-1}M_5 \) being found numerically on the digital computer. An equation similar to Equation 5 is then established and expanded to first-order differential-equation set. The rest of the analysis for the incorporation of control-equipment equations, dynamic performance, and stability limits follows as before.

This area of investigation leads to best ways for coordinating and interconnecting, control systems for dynamic stability for multi-machine operation. It is to this area which the experiences, confidences and simplifications gained with a single machine can fruitfully be extended and which are of ultimate interest and concern.

B. Two-Machine System Equations

The phasor diagram of a two-machine machine presentation is given in Figure 14. A separate reference axis is given. The generating units are described by Equation 51.
IX. REMARKS AND CONCLUSIONS

A. Machine Variables and A-constants

Machine variables and A-constants for the two values of tie-line reactances used in this study are given in Figures 15, 16, 17, and 18. Being in per-unit, as experience develops, these values will become increasingly helpful in predicting stable operation. Programs given in Appendix C.

B. Operation with Voltage Regulator

Figures 19, 20, 21, and 22 give dynamic stability with the voltage regulator only and at the nominal setting. Power output, machine damping and tie-line reactances are varied. Figure 27 summarizes these results.

Stability improves as unity power factor is approached from 0.90 power factor lagging with lighter power output and the lower tie-line reactance. This was as expected. The 0.95 lagging power factor full-load point was reported unstable at the higher tie-line reactance though close to being stable. Varying the damping had little effect on dynamic stability agreeing with Concordia's finding (6).

C. Operation with Voltage Regulator and Governor

Figures 23, 24, 25, and 26 give dynamic stability under the same conditions as section B above except with both the
governor and voltage regulator in operation. Figure 28 summarizes these results. An increase in range of stable operation to 0.975 power factor lagging was indicated.

It became evident that smaller increments of power factor should be taken at full-load output and the higher tie-line reactance. This evidenced stable operation up to and including 0.985 power factor lag, as given in Figure 30.

Lastly, it was desirable to ascertain if variations in voltage regulator settings would increase the power factor range on and above that given in Figure 29. Combinations of a few selected voltage regulator settings around the nominal setting produced results given in Figure 30. No further improvement over the nominal voltage regulator setting with the governor was evidenced. Computer time for this search was under 1.30 minutes.

D. General Observations

A derivative power signal was used for regulator damping. \( \frac{dP}{d\delta} \) was determined from differentiation but it could have been derived through the use of \( A_7 \) and \( A_8 \) constants also.

The representation of loads under transients around an operating point needs investigation. Constant current or constant mva rather than constant impedance may be more realistic.

In a multi-machine system involving more equations,
Kron's method of matrix reduction becomes a significant practical means for reducing the number of differential equations. The present eigenvalue routine handles a 30 x 30 matrix.

The margin between this dynamical approach to stability and a real-time steady-state study versus actual field tests is an area needing study and correlation.

By a combination of successive analysis, some synthesis, and judgment based on familiarity with both the problem and analytical approach, the system design and control schemes can be adjusted to give the maximum possible stability limit. VanNess (32) developed a program giving the sensitivity of eigenvalues with changes in system parameters to determine optimal design parameters and voltage regulator settings.

The new insights gained by the author in this study of the design and operation of modern-sized generating units has been marked. It has been stimulating to attempt to align academic thinking with present practices.

The method for extending the study to a two-machine system and ultimately n-machines using the multi-machine matrix approach, with iterated load flows, is included. This work has been left for future investigation. It is hoped valid simplifications in modeling will arise in this approach to stability. These are needed to counter the
complexities associated with an expanding A-matrix resulting from increased state-space equations needed to express and interrelate a multi-machine system.

The following data reported as unstable (X) in Figure 27

0.950 pf lag, X-line = 0.718 pu, power = 1.000 pu, D = 2
0.950 pf lag, X-line = 0.718 pu, power = 1.000 pu, D = 3
0.975 pf lag, X-line = 0.414 pu, power = 1.000 pu, D = 2

are very close to stable and undoubtedly incorrect due to round-off error in finding the eigenvalues.
Figure 15. Machine variables for various armature power factors. Angles are in degrees and all other variables are in per-unit on machine rating base. Constant power output and constant 1.0 per-unit infinite bus voltage. Line reactance (X-line) = 0.414 pu.

X. LITERATURE CITED

XI. ACKNOWLEDGMENTS

The author wishes to express his appreciation to his major professor, Dr. P. M. Anderson, for his suggestions and encouragement throughout the investigation. The author also wishes to thank Dr. R. J. Lambert for his help and advice on numerical analysis problems, and Mrs. Donald P. Smith (June Smith) for assistance in finding and using computer programs. Finally, the author wishes to thank Mr. G. L. Landgren of the Systems Planning Division of the Commonwealth Edison Company for data and his assistance which added practical and personal stimulus to this investigation.
XII. APPENDIX A, LIST OF PRINCIPAL SYMBOLS
(Second column is the Fortran program name)

**Generator and Transmission Line**

Values are in pu on the machine base unless otherwise noted. Direct axis is denoted by d. Quadrature axis is denoted by q.

- **p.f.** PF  Power factor
- **r.f.** RF  Reactive factor
  - SF  Complex of (PF,RF)
- **$V_b$** VB  Magnitude of infinite bus voltage
  - VBR  Real part of VB
  - VBJ  Imaginary part of VB
  - VBB  Complex of (VBR,VBJ)
- **$V_t$** VT  Magnitude of generator terminal voltage; also real part of VT (VT taken as reference axis)
- **$Y_{sh}$** YS  Half of adjusted shunt admittance of the transmission line
- **$Z_L$** ZL  Complex adjusted impedance of transmission line
- **$I_{sh}$** AIS  Complex current through YS
- **$I_b$** AIB  Complex current through ZL
- **EPA** Complex voltage behind Potier reactance
- **$E_p$** EP  Magnitude of EPA
- **$X_p$** XP  Potier reactance
  - AMPP Complex generator current with respect to VT
I  AMP  Armature current, (magnitude of AMPP)
\( r_e \)  RE  Magnitude of the real part of ZL
\( x_e \)  XE  Magnitude of the imaginary part of ZL
\( r_a \)  RARM  Resistance of armature
\( r_d \)  RD  Resistance of armature, d-axis
\( r_q \)  RQ  Resistance of armature, q-axis
\( x_d \)  XD  Reactance of generator, d-axis
\( x_q \)  XQ  Reactance of generator, q-axis
\( x_d' \)  XDD'  Transient reactance of generator
\( R_d \)  RRD  RD + RE
\( R_q \)  RRQ  RQ + RE
\( X_d \)  XXD  XD + XE
\( X_q \)  XXQ  XQ + XE
\( p \)  AMW  Power output, mva x p.f.
\( D \)  D  System damping, including effect of damper circuits
\( H \)  Inertia constant, mws/mva
\( f \)  Frequency, 60 HZ
\( M \)  AM  H/\( \pi f \)
\( \tau_f \)  TF  Open-circuit generator-field time constant, sec.
\( \tau_{dz} \)  TTDZ  Effective field time constant, sec.
\( \phi \)  PHIR  Angle between \( V_t \) and I, rad.
\( \delta_b \)  DELBR  Angle between \( V_t \) and \( V_b \), rad.
\( \delta \)  DELR  Angle between \( V_b \) and q-axis, rad.
\( \delta_q \)  DELQR  Angle between \( V_t \) and q-axis, rad.
\( \delta_t \)  DELTR  Angle between I and q-axis, rad.
\( \delta_I \)  
Angle between \( V_t \) and infinite-bus ref. axis

\( I_d \)  
AMPD d-axis component of I

\( I_q \)  
AMPQ q-axis component of I

\( V_d \)  
VD d-axis component of \( V_t \)

\( V_q \)  
VQ q-axis component of \( V_t \)

\( \psi_d \)  
PSID d-axis component of flux-linkages

\( \psi_q \)  
PSIQ q-axis component of flux-linkages

\( \psi_f \)  
Field flux linkages; \( \psi_{fd} = \psi_f x_{fd}/x_f \)

\( A_1 \ldots A_1 \ldots \) Machine coefficients related to the operating point

\( x_f \)  
Reactance of field winding

\( x_{fd} \)  
Mutual reactance between field and d-axis armature winding

\( i_f \)  
Field current; \( i_{fd} = i_f x_{fd} \)

\( v_f \)  
VF Field voltage

\( v_{fd} \)  
EFD \( V_f x_{fd}/r_f \)

\( r_f \)  
Resistance of field winding

\( T_m \)  
Mechanical torque

\( T_e \)  
Electrical torque

\( T_a \)  
Accelerating torque

\( p \)  
d/dt

\( \lambda \)  
Eigenvalues

\( A \)  
Matrices
Excitation System

A. General Non-linear System Equations

Using Park's notation \((25, 26)\) with direct and quadrature-axis windings, the equations relating machine fluxes and currents are

\[
\begin{pmatrix}
\psi_{fd} \\
\psi_d \\
\psi_q
\end{pmatrix} = \begin{pmatrix}
1 & - (x_d - x_d') & 0 \\
1 & -x_d & 0 \\
0 & 0 & -x_q
\end{pmatrix} \begin{pmatrix}
i_{fd} \\
i_d \\
i_q
\end{pmatrix}
\]  

(54)

where

\[
x_d' = x_L = x_d - \frac{x_{2d}^2}{x_f}
\]

\[
i_{fd} = x_{fd} i_f
\]

\[
\psi_{fd} = \frac{x_{fd}}{x_f} \psi_f
\]

\(\psi_{fd}\) is the variable representing the per-unit field flux linkages dependent upon the field/armature mutual reactance and field leakage reactance ratio.

The following assumes that voltages induced in the armature do not vary from voltages induced at synchronous speed, and that the armature voltages induced by the rate
change of flux linkages during rotor oscillation are negligible compared to those generated by the synchronous rotating flux.

\[
\begin{bmatrix}
    v_{fd} \\
    v_d \\
    v_q
\end{bmatrix} =
\begin{bmatrix}
    1 + \tau_f p & -\tau_f p(x_d - x'_d) & 0 \\
    0 & -r_d & x_q \\
    1 & -x_d & -r_q
\end{bmatrix}
\begin{bmatrix}
    i_{fd} \\
    i_d \\
    i_q
\end{bmatrix}
\]  

(55)

where

\[
v_{fd} = \frac{x_{fd}}{r_f} \quad v_f = (1 + \tau_f p) i_{fd}
\]

When the machine is considered to be connected to an infinite bus, proceeding from the internal machine conditions to that of the equivalent network, the following equations can be deduced from Figure 1.

\[
\begin{align*}
    v_d &= v_b \sin \delta + r_e i_d - x_e i_q \\
    v_q &= v_b \cos \delta + x_e i_d + r_e i_q
\end{align*}
\]  

(56)

The restraints on the change of rotor position, due to machine inertia and system damping, are expressed as

\[
M_p^2 = T_a = T_m - T_e
\]

or, more generally,

\[
(M_p^2 + D_p) \delta = T_m - (\psi_d i_q - \psi_q i_d)
\]  

(57)
and the terminal conditions

$$v_t^2 = v_d^2 + v_q^2$$
$$r^2 = i_d^2 + i_q^2$$

(58)

The above equations define the state of the machine with no control loops present.

B. A-constants

The A-constants derived in Equation 4 and given in Equation 5 are as follows from Laughton (21):

$$A_1 = \left(\frac{V_b}{-R_d R_q - X_d X_q^r}\right) \left\{ (\psi_q + i_q x_q') (R_q \cos \delta - X_q \sin \delta) \right. $$
$$+ \left( \psi_d + i_d x_d' \right) \left( R_d \sin \delta + X_d' \cos \delta \right) \left\} \right.$$ 

$$A_2 = \left(\frac{1}{-R_d R_q - X_d X_q^r}\right) \left\{ \psi_d + i_d x_d' R_d + i_q (R_d R_q + X_d X_q e') - \psi X_q \right\}$$

$$A_3 = \left(\frac{1}{-R_d R_q - X_d X_q^r}\right) \left\{ V_b \left( x_d - x_d' \right) \left( R_q \cos \delta - X_q \sin \delta \right) \right\}$$

$$A_4 = \frac{R_d R_q + X_d X_q}{-R_d R_q - X_d X_q^r}$$

$$A_5 = \frac{1}{-R_d R_q - X_d X_q^r} \frac{V_b}{V_t} \left[ -v_d \left( x_q' X_{q q} + r_d R_q \right) \cos \delta + \left( r_e x_q - r_d x_q \right) \sin \delta \right]$$

$$- v_q \left( r_e x_q' - x_e r_q \right) \cos \delta + \left( -x_q^r X_d - r_q R_d \right) \sin \delta \right\}$$
\[ A_6 = \left( \frac{1}{-R_d R_q - X_d X_q^*} \right) \left\{ \frac{-v_d}{V_t} (r_e x_q - r_d x_e) - \frac{v_q}{V_t} (r_e R_d + x_e x_q) \right\} \]

\[ A_7 = \left( \frac{1}{-R_d R_q - X_d X_q^*} \right) V_b \left\{ \frac{-i_d}{I} (-R_q \cos \delta + X_q \sin \delta) \right\} \]

\[ A_8 = \left( \frac{1}{-R_d R_q - X_d X_q^*} \right) \frac{-i_d}{I} X_q - \frac{i_q}{I} R_d \]

Also, the transient field time constant defined by

\[ \tau_{dz}' = \frac{R_d R_q + X_d X_q^*}{R_d R_q + X_d X_q^*} \tau_f \]

reduces the second row, second column diagonal element in Equation 4 to

\[ -A_4 (1 + \tau_{dz}' P). \]
