On-farm Food Safety:
Cleaning and Sanitizing Guide

Using good sanitation practices during production, harvesting, and packaging can help reduce the risk of microbial contamination of fresh produce. Soil, fertilizers, harvesting equipment, water, workers, or animals such as livestock, pets, and pests can be sources of harmful microorganisms that cause foodborne illness. Surfaces that come in contact with produce must be washed, rinsed, and sanitized regularly. Employees need to understand and use appropriate food handling practices.

Food Contact Surfaces
Any surface that comes in contact with food, either directly or indirectly, is a food contact surface. Examples include preparation tables, spinners, food bags, and cartons for transporting produce. Food contact surfaces should be smooth and nonporous to allow for easy and effective cleaning. Rough surfaces, such as wood, can harbor dirt and microorganisms. Stainless steel tables and counters are commonly used in foodservice and processing facilities due to durability and ease of cleaning.

Other surfaces that can come into contact with product include containers for harvesting and transportation, tables in packing areas, bags and other packaging materials, conveyors, processing equipment, employee aprons, outerwear, and gloves. Hands also may come into contact with the food. For more information about food handling practices, see “On-farm Food Safety: Food Handling Guide” (PM 1974b).

Cleaning
Cleaning means removing soil and residues. For product (fruits and vegetables) the cleaning steps vary with how dirty the product is, and the tenderness and perishable nature of the food. For example, root vegetables often require initial rinsing, scrubbing, followed by one or two additional rinses to remove soil residue, while only rinsing can be safely used on leafy green vegetables. Fruits and vegetables that grow well above the ground may be brushed or wiped when soil and other residue are minimal. Other tender or highly perishable products such as strawberries or raspberries should not be washed with water until just prior to use, as should all fruits and vegetables. When water is used for cleaning, it should be potable (safe to drink). New research shows that for certain vegetables, such as tomatoes, bacteria can be pulled into openings if the wash water temperature is colder than that of the produce item.

Cleaning of food contact surfaces means removing soil and residues. This involves a three-step process of rinsing away surface debris, washing and scrubbing with soap or detergent, followed by rinsing with clean potable water. Rinsing surfaces thoroughly is important so that any detergent residue is removed.

Under certain conditions, microorganisms (bacteria, yeasts, and molds) can form invisible films (biofilms) on surfaces. Biofilms can be difficult to remove and usually require cleaners (for physical removal) as well as sanitizers (for killing of biofilm microbes.)

Sanitizing
Sanitizing is the process of treating a food contact surface with a sanitizing solution that will kill most microorganisms or reduce them to a non-harmful level. For sanitizers to be effective, surfaces must first be cleaned, because soil and soap residues can make the sanitizing solution less effective.

• **Sanitizing** is a process that reduces the contamination level of a product or food contact surface surface by 99.999 (5-log reduction) percent in 30 seconds.

• **Sanitizer** is a chemical compound designed to kill microorganisms. Chlorine bleach (sodium hypochlorite concentrations 5.25 to 6.5 % in liquid form) and quaternary ammonium compounds (quats) are commonly used sanitizers for food contact surfaces. Chlorine and hydrogen peroxide, at proper concentrations, can be used for food products.
How to use test strips
• Make sure the test strip is appropriate for the type of sanitizer.
• Prepare the sanitizing solution.
• Dip a strip into the solution.
• Compare the color the strip changed to with the guide on the outside of the package to determine the solution strength.
• Record sanitizer concentration.

Cleaning tips
• Have tools, supplies, and waste receptacles easily available for employee use.
• Make sure waste receptacles are regularly emptied and cleaned.
• Have a place to properly store all equipment at the end of the day.
• Encourage employees to share ideas related to cleaning and sanitizing.
• Look for potential problems when walking through your operation.
• Evaluate all cleaning and processing equipment and utensils daily.
• Conduct a visual inspection to make sure surfaces are in good condition and cleaned and sanitized regularly.
• Establish a cleaning and sanitizing schedule for equipment and food contact surfaces.

However, excessive concentrations may damage product tissues and/or lead to toxic levels. Producers should check with regulators in their areas regarding approved agents. It is recommended only registered formulas be used.

• Sanitizing solution is the mixture of a specific amount of a sanitizer with potable water, according to the directions given by the manufacturer to create the proper concentration.

Sanitizing solutions gradually lose effectiveness over time. As the solution is continually exposed to air or organic materials, reactions cause some of the chemical to dissipate. The best way to check whether a sanitizing solution is effective is to use a test strip. Sanitizing solutions should be made and checked at least daily. They also should be recorded. (See sidebar to left for an example of chlorine test strips).

Choosing a Sanitizer
Producers should select a sanitizer based on these characteristics: safety for workers and the environment, stability, water quality and pH, and non-corrosiveness. Several types of sanitizers are available for products and/or food contact surfaces: chlorine (50 – 200 parts per million or ppm), quaternary ammonium or quats (see label for recommended concentrations), hydrogen peroxide, and new generation food-grade vegetable washes. (See sidebar on page 3).

New generation food-grade vegetable washes, such as PRO-SAN®LC, sanitize fresh produce and produce contact surfaces and are biodegradable. Chlorine and hydrogen peroxide are commonly used for products because they are readily available and cost effective. For a complete list of approved sanitizers for products and food contact surfaces, check with state and federal regulatory agencies.

Sanitizers may have multiple uses. For example, chlorine can be used on fresh produce or on food contact surfaces, depending on the concentration. Room temperature water should be used to minimize chlorine loss in the solution. The proportion of sanitizer to water must be accurate to make sure the solution will be effective and avoid damage to products and consumers. A common recipe for a chlorine based sanitizing solution is 1 tablespoon household bleach (non-scented) per 1 gallon room temperature water. This will result in a solution of 100 ppm. A range of 50 – 100 ppm is recommended for food contact surfaces. This solution is applied as a fine spray in the final step of the cleaning process and should not be wiped or rinsed off. Surfaces should be allowed to air dry. We recommend 100 – 200 ppm chlorine solution for products. Mixing up to 2 tablespoons per gallon of water (200 ppm solution) can be used because organic materials, like soil, will break down effectiveness of the chlorine quickly. Removing as much soil as possible from the product prior to washing, and changing chlorinated wash water frequently is recommended. A final rinse with potable water can be used on the produce but is not necessary.

Chlorine bleach can be purchased in several concentrations of the active ingredient, sodium hypochlorite. A typical
Sample Chemical Sanitizer Monitoring Form

<table>
<thead>
<tr>
<th>Date</th>
<th>Initials</th>
<th>Test Strip Result</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>8/15/10</td>
<td>DH</td>
<td>Chlorine 50 ppm—OK</td>
<td>Surfaces</td>
</tr>
<tr>
<td>8/15/10</td>
<td>DH</td>
<td>Chlorine 200 ppm—OK</td>
<td>Product</td>
</tr>
</tbody>
</table>

Directions:
1. Complete this form daily.
2. Record date, your initials, and test strip result.
3. Indicate whether the test strip turned the appropriate color to meet the sanitizer concentration standard. The result is either “OK” or “CHANGED.” If the solution is changed, indicate corrective action on the form.
4. If the sanitizer solution is redone, log the new concentration on the form.

Set up Cleaning and Sanitizing Schedule
The key to effective cleaning and sanitizing is making these practices part of normal operations. Equipment should be cleaned from top to bottom to avoid re-soiling already cleaned surfaces. In general, four questions need to be answered.

1. **What** should be cleaned?
2. **How** should each piece of equipment or food contact surface be cleaned and sanitized?
3. **When** should equipment be cleaned? Daily, weekly, as needed?
4. **Who** is responsible? Is a specific person or a position responsible for each cleaning task? Who will check to make sure the list is done according to schedule?

Many steps can be easily overlooked during cleaning. Action items in the schedule should be incorporated into regular duties of workers. Workers should initial the form to document that the task is completed. Regular cleaning reduces the buildup of microorganisms.

Visit www.iowahaccp.iastate.edu for sample cleaning procedures, schedules, and monitoring forms.
Summary
Cleaning and sanitizing are part of an overall food safety plan to provide the safest and best quality fresh fruits, vegetables, greens, and herbs to customers. Checklists, standard procedures, and schedules are typically the best ways to communicate information to employees and document that proper cleaning and sanitizing practices are followed.
