Summary and Implications
Higher prices for corn and increasing supplies of DDGS have generated questions about feeding DDGS to market swine. The objective of this study was to evaluate various programs to maximize DDGS feeding to finishing pigs in bedded hoop barns.

Materials and Methods
For each trial, crossbred finishing pigs (n = 60) were allocated to six pens with five barrows and five gilts per pen (54.4 lb avg. weight). The project consisted of three identical sequential trials beginning in April 2008. The project was conducted during 2008 and 2009 at the ISU Western Research Farm, Castana, IA. The pens were in small hoop barns with two pens per barn. Each pen had a self-feeder and an automatic waterer and was bedded with straw. The pigs were from the ISU Swine Nutrition Farm, Ames, IA and were the progeny of white sows crossed with Duroc terminal boars.

Each pen was assigned to one of three dietary treatments—continuous 20% DDGS (Cont), a step-up program from 0% to 30% DDGS (Step), and a high DDGS program that rapidly got pigs to 30% DDGS (High). All treatments were fed a 20% DDGS diet for the last phase of the trial. There were 4 dietary phases in the 98-day trial. Phase 1 and 4 were each 21d. Phase 2 and 3 were each 28d. The diets were pelleted and fed ad libitum. Within each phase, the diets were formulated to be equal in apparent digestible amino acids—lysine, threonine, and tryptophan.

The pigs consumed the diets readily with no apparent problems making the transition among the diets. Feed intake (ADFI), growth (ADG), and feed per liveweight gain (F/G) did not differ among treatments (P > 0.05). No major differences were noted in backfat thickness (BF) and loin muscle area (LMA) (P > 0.05). Also, based on the means of fatty acid saturation, iodine values, and belly flop scores of selected pigs in trial (one, two or three), the differences in unsaturation percentages, iodine value and belly flop scores between treatments were minor.

On average, a pig fed the continuous program consumed 119 lb of DDGS or 20% of the total feed over the 98-day feeding trial (from 54 to 274 lb). A pig fed the Step-up program consumed 106 lb of DDGS or 17% of the total feed. A pig fed the High program consumed 162 lb of DDGS or 26% of the total feed. This work suggests that diets and feeding programs can be designed to increase DDGS usage by market swine without negatively affecting pig performance. Also formulating diets on apparent digestible amino acid content may be advantageous when using DDGS on swine diets. The pelleted diets worked well with no problems in feed flow or fines separation.

Introduction
Iowa’s ethanol industry continues to expand rapidly. A major coproduct of ethanol production is dried distillers grains with solubles (DDGS). Higher prices for corn and increasing supplies of DDGS have generated questions about feeding DDGS to market swine. The objective of this study was to evaluate various programs to maximize DDGS feeding to finishing pigs in bedded hoop barns.
samples of belly fat (4 pigs per treatment) using gas chromatography techniques and fatty acids were grouped as saturated (SFA), mono unsaturated (MUFA), and poly unsaturated (PUFA). Saturated fats are harder and unsaturated fats are softer and oilier. Iodine value was calculated based on the fatty acid profiles and is a measure of fat unsaturation. The higher the iodine value the softer and oilier or more unsaturated is the fat.

Results and Discussion

The pigs consumed the diets readily with no apparent problems making the transition among the diets. Results are shown in Table 4. Feed intake (ADFI), growth (ADG), and feed per liveweight gain (F/G) did not differ among treatments (P > 0.05). No major differences were noted in backfat thickness (BF) and loin muscle area (LMA) (P > 0.05).

On average, a pig fed the continuous program consumed 119 lb of DDGS or 20% of the total feed over the 98-day feeding trial (from 54 to 274 lb). A pig fed the Step-up program consumed 106 lb of DDGS or 17% of the total feed. A pig fed the High program consumed 162 lb of DDGS or 26% of the total feed. This work suggests that diets and feeding programs can be designed to increase DDGS usage by market swine without negatively affecting pig performance. Also formulating diets on apparent digestible amino acid content may be advantageous when using DDGS on swine diets. The pelleted diets worked well with no problems in feed flow or fines separation.

Based on the means of fatty acid saturation, iodine values, and belly flop scores of selected pigs in trial two (Table 5), the differences in unsaturation percentages, iodine values and belly flop scores among treatments were minor. Even though all pigs were fed the same level of DDGS during the final three weeks of the trial, the more DDGS fed during the entire feeding period the more unsaturated the fat depots became. This suggests that the pigs should have been fed the last phase longer to allow more time for the fat to become less unsaturated.

Acknowledgements

The authors gratefully acknowledge the cooperation of the Arcadia Co-op, Arcadia, IA; Amaizing Energy ethanol plant, Denison, IA and Farmland plant, Denison, IA; and Arlie Penner for data summarization. The authors also recognize Dr. Roger Johnson, director of Pork Quality, and Suzanne Myers, both of Farmland Foods for coordinating the fat sampling and analysis.
